THE INDICATION OF NEPHROSTOMY PRELIMINARY TO URETERO-RECTONEOSTOMY

FRANK HINMAN, M.D.
SAN FRANCISCO

The transplantation of ureters into the bowel is regarded as justifiable in a relatively small group of cases. Freed from the many dang[illegible] [illegible]oth immediate and remote, the applicability wo[illegible] immediately to a respectable figure. As it [illegible] procedure may be used only as a desperate means of relief of last resort.

The widest application has been in exstrophy of the bladder and similar anomalies, and no doubt a short life of continence and comfort is preferable to the shorter one of pain and misery inevitable to the unfortunate children born with this deformity. Yet ureterorectal transplantation for exstrophy is not an ideal surgical procedure nor ever will be even if freed from its present dangers. Such an individual is at once removed from the service of modern urologic methods, well illustrated by a patient of my own who had lived six years comfortably with the ureter of the only remaining kidney emptying into the rectum when she was suddenly taken with fever without localizing symptoms. She lived in the country and did not come in until in the early stage of uremia. Even then had we been able to catheterize the ureter and apply preparatory catheter treatment, the kidney most probably could have been reactivated. Roentgen-ray examination showed a suspicious shadow, a[illegible] the exploratory operation with removal of a large stone that completely blocked the upper ureter failed to relieve the anuria. The case shows how intestinal transplantation ties our hands in recognizing and caring for subsequent renal complications and, if for no other reason, renders ureterorectoneostomy for exstrophy objectionable. A surgical victory over this defect is inevitable, but there can be none without restoration to near normal relationships. What has been done for cleft palate is possible for cleft symphysis. Orthopedic measures must be applied. The prolonged tedious and continuously applied methods of straightening teeth and jaws should serve as an example and stimulus. The difficulty is largely that we each get too few patients to work with, the majority of whom are too poor to stand the expense of years of treatment and the rest unwilling. Two patients that were started on this plan by me went across town and had ureters transplanted. The suggestions of Hugh H. Young [1] and of J. E. Burns [2] are hopeful.

TRANSPLANTATION OF URETERS IN ACQUIRED CONDITIONS

Certain acquired conditions form another group in which transplantation of the ureters or ureter sometimes becomes a necessity or is desired in order properly to complete other operative measures. Cancer of the bladder may be so extensive as to necessitate total cystectomy in order to offer any hope of cure, thus requiring the transplantation of the ureters to the skin or rectum. And tuberculosis of the bladder is often found to be progressive even after the one tuberculous kidney has been removed, rendering the patient miserable because of pain and frequency, and, what is more serious, sometimes leading to a progressive destruction of the remaining kidney by hydronephrosis through constriction of the vesical end of the ureter. We have had three such cases treated for long periods to relieve the bladder infection without benefit, during which time kidney function was seen to fall gradually, in one case to 5 per cent in two hours, through back pressure destruction. All attempts to dilate the lower ureter were unsuccessful. In all three of these cases the ureter has been successfully transplanted to the rectum. One patient, mentioned above, lived six years in comfort and cleanliness and then died of the stone complication. A necropsy found that the ureterorectal transplant was in perfect condition, that the rectal mucosa was of normal appearance (fig. 1) and that the kidney pelvis was not dilated beyond what would be expected from the stone obstruction that had been a secondary complication. The kidney itself appeared unusually well preserved (fig. 2). At the time of transplantation the ureter was markedly dilated and at necropsy it was found that this condition had not shown any material shrinkage. This is to be expected from results that have been obtained experimentally. A ligature placed at the lower end of the ureter in experimental hydronephrosis causes a progressively developing hydro-ureter. In the repair experiments in which this hydro-ureter was retransplanted to the bladder with renal repair there was marked shrinkage of the kidney with retention of the kidney shape, but little change subsequently in the hypertrophied and dilated ureter.

It was also noted in these studies that when an experimental animal which had had one ureter completely ligated was opened, the hydro-ureter showed active peristalsis on the slightest stimulation, even in those advanced stages of complete hydronephrotic atrophy. But in those cases of secondary atrophy and not of repair following the ureterocystoneostomy the ureter is found also to undergo shrinkage and atrophy, and this would seem to be largely a disuse atrophy. In another case in every way similar to the foregoing, the patient lived over two years and died of a complicating bilateral pneumonia unrelated to his urinary condition.

[2] Burns, J. E.: A New Operation for Exstrophy of the Bladder, J. A. M. A. **82**: 1587-1590 (May 17) 1924.

A phenolsulphonphthalein test by rectum done just a few weeks previously showed a 45 per cent output. Unfortunately, in this case a postmortem examination was not obtained. In a third case the hydro-ureter of the remaining nontuberculous kidney, already hydronephrotic from the obstruction at the vesical end of the ureter, as a result of the constriction of the tuberculous bladder, has been transplanted to the rectum within the last few months. In this last case preliminary nephrostomy was performed, a discussion of the advisability of which is my object in this communication. At the time of this nephrostomy, careful inspection of the kidney showed no evidence of any tuberculosis. The finding at necropsy (case 1) and at operation (case 3) of a hydronephrosis without tuberculosis is solid food for thought. Statistics tell us that in renal tuberculosis nephrectomy before vesical involvement is curative in practically 100 per cent, but after vesical ulcers have appeared, in only about 60 per cent. This finding raises the question of whether a good proportion of the 40 per cent that succumb following nephrectomy for renal tuberculosis do not die because of a progressive hydronephrosis of the remaining kidney from obstruction due to the progressive contracture and fibrosis of the badly infected bladder. It also raises the question as to whether a preliminary nephrostomy alone might be of benefit in these cases in putting the bladder at rest. Subsequent ureterorectal transplantation might not then be required.

CANCER OF UTERUS

Cancer of the uterus may be so located as to spread early to neighboring organs such as the rectum and bladder, and in order to do a radical resection of the cancer it would sometimes be necessary to sacrifice both bladder and rectum. The ureters are sometimes unintentionally injured or resected, and the usual procedure has been to tie off the ureter if recognized at the time, or do a nephrectomy later to close the urinary fistula, if only one has been injured. Were uretero-intestinal transplantation feasible, much more radical operations on both the uterus and bladder would be possible. A large vesicovaginal fistula subsequent to hysterectomy and the use of radium for an extensive cancer of the cervix came to us within the last few years for repair. On the first examination, fragments taken from the area failed to show any evidence of malignancy and it was thought that the fistula was largely the result of the radium burn. An attempt to close the fistula in the usual manner resulted in failure. The patient returned several months later and it was found that the opening was larger than on the previous entrance, pain was much more severe, and all the urine dribbled into the vagina; curettings from the area showed definite malignancy. Careful roentgen-ray and other studies failed to show any evidence of metastases to any distant point. After consultation with the general surgeons and gynecologists, it was decided that the only relief to be offered would be by ureterorectal transplantation and then, should progress of the case justify it, a more radical resection of the involved area of the pelvis could be done. The right ureter, which was considerably dilated, was first transplanted. The patient's convalescence was complicated by pronounced nausea and vomiting without fever or abdominal distention, counteracted only by a retention duodenal tube; but without any other apparent complications she gradually failed and died on the thirteenth day after operation. A complete necropsy failed to show any evidence of metastases from the primary site of growth, which, however, was quite extensive, involving the bladder and the vagina, but not the rectum. The ureteral transplant was apparently in good condition and quite patent, and there was no ascending infection to the kidney nor any local peritonitis. Urinary drainage through the rectum had been noted before death. No cause for death other than alkalosis could be given.

OTHER CONDITIONS IN PELVIS

There are other surgical and pathologic conditions in the pelvis and about the lower end of the ureters in which either accidentally or purposely unilateral partial resection or destruction occurs, and in these conditions retransplantation to the rectum would be indicated, provided the procedure were safe, in preference to simply tying off the ureter or performing nephrectomy. In one case of our own of extensive tuberculosis of the seminal vesicles, the ureter on the left side was accidentally injured in removal of the large tuberculous vesicle on this side. Urinary fistula resulted, and the question arose as to what should be done with this open ureteral end. With partial or complete closure of the drainage tract, rise of temperature and pain would occur, relieved only by the removal of the obstruction by dilation or curettage of the urinary fistula. Urologic study showed that the opposite kidney was perfectly normal and was gradually undergoing compensatory hypertrophy. Several cystoscopic examinations showed that the bladder was absolutely clear and that there was no opening or rupture of the bladder that would account for the urinary drainage through the perineum. At no time was one able to catheterize the left side, the side on which the ureter had been either cut or injured. Finally nephrectomy was decided on as the safest procedure, and it was found after removal that this kidney showed an early, rather acute type of tuberculosis and there was definite evidence of ascending infection. We have seen a number of similar cases in consultation with gynecologists in which the lower end of the ureter has been accidentally injured or resected, in which if unilateral the course is similar to that of the foregoing case. In most of these cases, nephrectomy later has seemed the advisable method of procedure. It is rarely possible to bring the ureter to the bladder for ureterocystoneostomy and usually impossible to bring the divided ureteral ends together for suture. This subject is of particular interest in view of the general controversy as to the result of complete ureteral ligature in man, most textbooks and many eminent surgeons stating definitely that there will be no bad effects but that if the ureter is completely tied the kidney will undergo a silent primary atrophy. This is in direct opposition to all experimental results, and clinical facts definitely refute it. Hydronephrosis will almost invariably result although a secondary atrophy may subsequently develop; but this secondary atrophy is an entirely different thing from a primary atrophy. Of seventeen cases of ureteral ligation in which the kidney was later examined, fourteen showed a definite hydronephrosis, and of sixty-four cases of ligation of one ureter reported in the literature, only twenty patients are said to have later experienced no discomfort or deformity.[3]

CANCER OF PROSTATE

The success of Coffey[4] in the radical resection of the rectum for cancer raises the question whether our treatment of cancer of the prostate has been sufficiently radical. It is the exception to see cancer of the prostate early enough to permit the radical operation of Young or Geraghty's modification. With the urine safely diverted elsewhere, the prostate, seminal vesicles, bladder and the pelvic lymphatics of primary drainage from the prostate could be easily removed *en masse*. Except for the pudic and sacral branches, which arise highest and could easily be preserved, the whole anterior division of the internal iliac artery and vein could be ligated at the time of ureteral implantation, which would render quite easy the later perineal resection of the whole mass. At the time of the ureteral transplantation it would of course be advisable to free the bladder thoroughly and leave in suprapubic drains. An unsuccessful attempt to perform this procedure does not disprove its logic in a properly indicated case. This failure was in a man of good general health and strong constitution who had quite an extensive carcinoma of the prostate that spread well up to the base of the bladder, involving both seminal vesicles but in whom evidence of general metastasis was absent. Radium in heroic doses had been tried for a number of months without any apparent effect on the spread of the growth. He suffered considerably even on the retention catheter. His kidney function was normal. He was quite anxious when the situation had been thoroughly explained to him to have the operation outlined above done. Following the transplantation of the right ureter, he developed an acute bronchopneumonia and died. At necropsy no metastases were found, the transplant was in good condition except that there was some localized peritonitis, and he had an extensive bronchopneumonia. Had we known as much then as now about intestinal transplantation, his chances would have been materially improved.

So far as indication for performing ureterorectoneostomy is concerned, the advantage of being able to divert the urine safely is at once apparent for a great deal of the radical surgery of many pelvic conditions.

ADVANTAGES OF THIS SITE OF TRANSPLANTATION

Leaving for discussion later the technical difficulties and dangers of ureterorectal transplantation, it is well to be convinced that this site of transplantation is preferable to any other. The miserable condition of exstrophy patients has been the motive for many different attempts of plastic repair. No mechanical device intended to protect the sensitive exposed mucous membrane and to collect the urine has been satisfactory, so that ever since Simon[5] in 1815 first suggested implantation of the ureters for exstrophy, an amazing number of different types of operation have been suggested. Aside from implanting the ureter directly into the bowel, isolated pieces of uninfected small intestine with the idea it would serve as a bladder, the use of the vagina or gallbladder for the same purpose or resection of the intestine low in the rectum and making a double outlet in the sphincter ani, one for urine and the other for feces, have been at various times attempted but have all failed as a result of the stasis of urine inherent in any of these procedures. Transplantation to the skin carries the objection of the necessity of wearing some kind of collecting device, and in the great majority of these cases also stricture formation and ascending infections are frequent. The most successful type of skin transplantation has been nephrostomy, in which a suitable apparatus can be fastened to the back and the urine collected by tubes that lead around to the front so that the patient can empty the artificial bladder as in a normal manner.

Young[6] has himself highly recommended nephrostomy in indicated conditions. As a permanent procedure it of course is not equal to intestinal transplantation, which gives continence, provided the dangers of the latter can be surmounted. There are good reasons why the rectum is the preferable site for direct implantation. The cloaca of amphibia, reptiles and birds forms the common receptacle for urine and feces, and the lowest subclass of mammals have the same condition. It has even been reported as an anomaly in the human fetus.[7] Fowler[8] has emphasized the physiologic significance of an empty rectum in the normal state between the acts of defecation, as pointed out by O'Beirne,[9] but these observations have not been entirely confirmed. However, in those cases in which ureters have been transplanted into the rectum there may be formed for all practical purposes two receptacles, the sigmoid for the storage of feces and the rectum for that of the urine acting only as a temporary receptacle for feces. Alvarez[10] has suggested that in these cases the irritation through accumulation of urine in the rectum may arrest the normal downward movement of feces sufficiently to cause a fecal collection in the transverse colon until that time in which the colonic irritation predominates and rushes the feces out in a bowel movement. Alvarez also regards the stormy sigmoid as unfit for ureteral implantation, as it is a free and very motile stretch of bowel. It worked very successfully, however, in case 1 (fig. 1). All things considered, the rectum is the preferable part of the bowel for implantation. Skin transplants have the objection of not providing continence and do not sufficiently reduce the dangers of obstruction from stricture or of ascending infection.

DIFFICULTIES

The difficulties of successful intestinal implantation of the ureter are both inherent and technical, and immediate and remote. The inherent objections are the placing of ureters into a continuously and highly infected field and in a position that removes them from subsequent treatment and study by urologic methods. The technical difficulties of immediate significance are not so great but that they can be overcome. The spread of infection, peritonitis, fecal fistula are dangers that are now little to be feared, thanks to Coffey's[11] suggestions. The obstruction from the immediate edema at the site of implantation unless means of protection are taken may lead to an acute and early ascending pyelonephritis or anuria, which has been guarded against heretofore by transplanting one ureter at a time. This temporary obstruction, however, is a real danger when there is only one kidney and it otherwise necessitates two operations which for some of the conditions, as indicated above, is considerable of a burden in preparation for the final operation. It means three major operations, the third and last the hardest. The remote dangers are obviously those of a pyelonephritis and of stricture or other obstruction leading to destruction by hydronephrosis or secondary atrophy. Most of these difficulties could easily be removed by implantation of the ureter into the sterile small intestine, but this is prohibitive because of complete urinary reabsorption.[12] The propriety and risk at any time of ureterorectoneostomy is brought home by this problem: Given an individual with two healthy kidneys, the lower ureter of one of which has been accidentally injured or cut necessitating transplantation, ligature or nephrectomy, which would you choose?

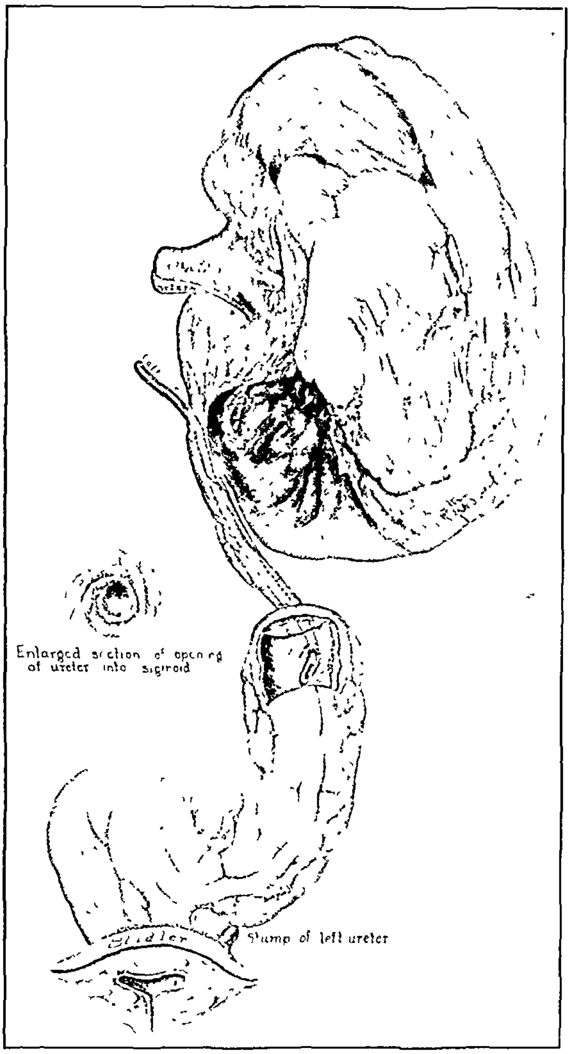

Fig. 1—Finding at necropsy in case 1, six years after ureterosigmoidoneostomy: The ureteral opening in the bowel is in perfect condition and quite patent The ureter was still dilated as about at time of transplantation. The stone that had produced the anuria causing death was located at the ureteropelvic juncture Kidney showed moderate hydronephrosis, probably more the effect of the stone blockage.

DEVELOPMENT OF TECHNIC

In the particular technic of transplantation, the greatest progress has come within the last few years. The surgical problem is to remove the dangers as just mentioned and be able to transplant the two ureters at one operation, which would be a big advantage if safe. It was in 1815 that Simon[5] first suggested the advisability of uretero-intestinal transplantation, but the procedure has never been general. Smith,[13] in 1879, advocated a carefully planned surgical procedure unsuccessfully, and no greater success was obtained by such eminent men as Trendelenburg.[14] A great stimulus came from Tuffier's[15] suggestion of implanting the ureter with its normal sphincter intact, a procedure practically applied by Maydl[16] in 1892 and rather widely made use of since, though not much within recent years. Anastomotic buttons after the manner of intestinal anastomosis have also been variously tried, notably by Frank[17] and Boari.[18] The modern method really started with Fowler's[8] suggestion in 1898, with the attempt to form a sphincter with valve action. Martin[19] added some technical improvements with the same idea of sphincter formation, the essential feature of which is that a direct ureteral implantation is made with the ureter running along an oblique muscular canal, perforating the bowel through a small opening in the mucosa.

The most valuable technical advances have come with the highly commendable work of R. C. Coffey, who places emphasis on the formation of a valve action as is normally present in the oblique passage of the ureter into the bladder, and who attempts to duplicate this valve of nature by having the ureteral end pass obliquely under the rectal mucous membrane for a few centimeters before opening into the intestinal lumen. This technical perfection satisfies the anatomic requirements fairly satisfactorily except that in those pathologic cases of large hydro-ureters it is much more difficult of execution, and in my experience it is questionable whether any true valve can be made to function in these cases in which the ureter is markedly dilated or as large as one's little finger. In the first hydro-ureter that I transplanted (case 1 above), either the attempt to follow Coffey's technic too literally or obstruction from edema led to an anuria necessitating reoperation on the third day, at which no effort of valve formation was made but the hydro-ureter was implanted directly and comfortably a little higher up and into the sigmoid just as one would do in ureterocystoneostomy. This particular technic was in this one case at least highly successful; the patient lived comfortably for six years, and at the necropsy a perfect result so far as the transplant is concerned was found. It was noted also that the ureter had shrunken practically none in this six year period (fig. 1).

Coffey also has recently perfected a means of preventing local spread of infection which renders the implantation much safer than heretofore. The means is quite simple; after the rectum has been freed it is clamped as high as conveniently can be, and through a rectal speculum previously placed through the anus the lower bowel is flushed clean by means of a trocar inserted under surgical asepsis by the operator into the bowel just below the clamp. In this way all the contents of the rectum can be flushed out and the cleansed rectum can then be packed with sterile gauze, so that there is no possibility of a gush of fecal material into the operative field at the time the rectal mucosa is opened for ureteral implantation. This is what occurred in a minor degree in one of the cases mentioned above in which the patient died of bronchopneumonia and showed at necropsy a localized peritonitis. Coffey has also suggested, and the method has been used successfully by himself and other operators, the use of tubes that are placed in the open ureteral end and then passed down *through the rectal speculum* to the outside so as to drain the transplanted ureter for the first few days after operation, thus removing the danger of the early obstruction from edema during the time of healing. This method was primarily proposed in order to enable double transplantation at the one operation. Tubes leading directly through the infected rectum, theoretically, at least, promote reflux around them of rectal contents to the renal pelvis. In pathologic kidneys with hydroureters, particularly if only one kidney is present, even these improvements fail to give complete protection against ascending infection. On removal of the tubes, one's bridges, as it were, are burned behind him. No treatment of the isolated kidney is now possible.

In those desperate cases in which one reasons that the patient may die after ureteral transplantation but he most certainly will die if the ureter is not transplanted, it would seem more logical from a surgical standpoint to perform nephrostomy as a preparatory measure to subsequent ureteral transplantation, should conditions then justify it. The lumbar drainage leaves an avenue of direct treatment and free outlet for the urine from the kidney. As a matter of fact, one could now do as he wished with the lower end of the ureter. Such nephrostomy drainage would do away with the danger of early ascending infection and of obstruction from the early edema during the time of healing, thus obviating the need of tubes and their dangers.

Through such a nephrostomy opening after ureteral transplantation the lower ureter can be flushed from above in the natural direction and, if necessary, its lower end gradually dilated by passage of catheters through the nephrostomy opening. In this treatment, of course, catheters should be drawn on through the rectum, and not back by way of the nephrostomy opening.

I have used preliminary nephrostomy in two cases of advanced tuberculosis of the bladder, one already mentioned, in which renal function had dropped but in which we were unable to demonstrate tuberculosis of the remaining but progressively atrophying kidney. Although the patient was in a very weakened condition and transfusion had to be done before nephrostomy, the intestinal transplantation two weeks later occasioned no reaction, and convalescence has been uneventful. In the other case the kidney was drained for almost three months through the nephrostomy tube in order by putting the bladder at rest to promote healing But, there being no improvement, the ureter was finally and successfully implanted into the rectum.

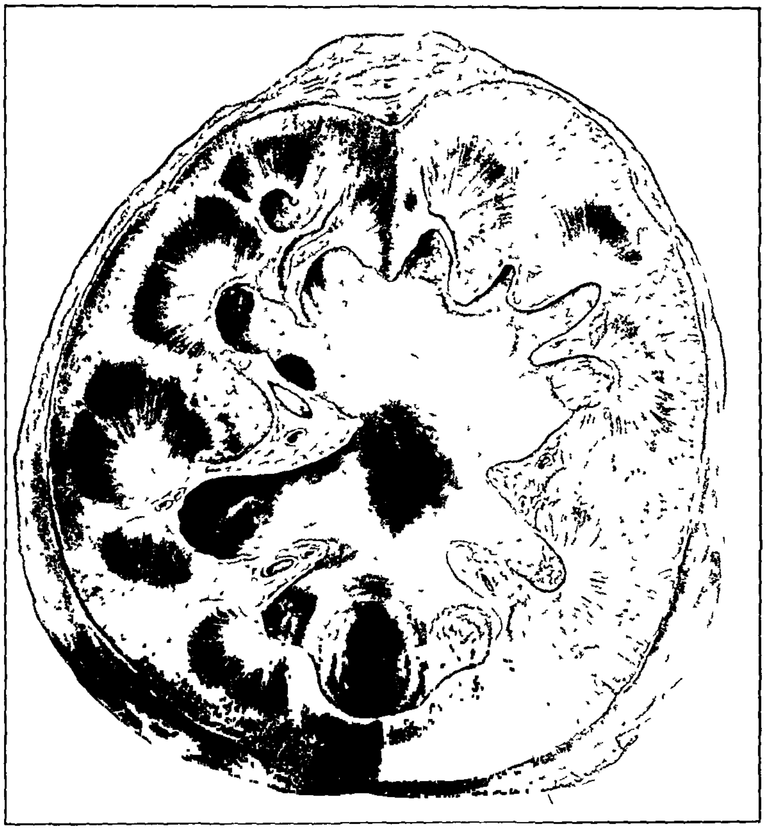

Fig 2 —Appearance of kidney removed at necropsy in case 1 There was no evidence of tuberculosis, and subsequent careful microscopic search failed to find any The renal parenchyma was in unusually good condition in view of the period of anuria and the irritation incident to the stone obstruction The hydronephrosis is partly the result of the original obstruction at the ureterovesical end before implantation of the ureter into the intestine but mostly from the more recent stone obstruction

INDICATIONS

It would hardly be indicated to perform nephrostomy in all cases in which ureteral transplantation seems indicated. In exstrophy when the ureters are usually of normal size and function, intestinal transplantation by the perfected method of Coffey is simple and usually quite satisfactory so far as immediate results are concerned. I have several patients now alive for many years in perfect health and comfort, the longest one eight years, the last examination of whom showed fairly normal function by rectum. Another patient who had both ureters transplanted two years ago has just had the bladder resected and a plastic operation done at the vulva. She has been in school and in apparently perfect health. A large series of successful cases are reported from the Mayo Clinic and by Lower and others.[20] However, ureterorectoneostomy is not the final surgical word in exstrophy. But in the acquired conditions in which ureteral transplantation is indicated, particularly if only one kidney remains and its ureter is hypertrophied and dilated, preliminary nephrostomy is a safeguard that will materially lower the immediate mortality of the procedure and greatly promote its ultimate success.

SUBCAPITAL FRACTURE OF THE NECK OF THE FEMUR[*]

ARMITAGE WHITMAN, M D.
NEW YORK

The question of the proper treatment for all varieties of fracture of the neck of the femur seems at last to have been settled. In other words, the abduction treatment—the Whitman method—has been accepted by surgeons acquainted with the treatment of fractures.

The subject of fracture of the neck of the femur in general, however, is still open to discussion. To make the subject as clear as possible, I think it advisable to adopt, instead of the time-worn and somewhat vague intracapsular and extracapsular fracture, the more definite French terminology. Fractures of the neck of the femur are classified by Delbet as (1) subcapital, (2) transcervical, (3) cervicotrochanteric and (4) pertrochanteric, as illustrated by figure 1.

This classification is important because opinion seems to be unanimous that the last two forms of the fracture will unite under any form of treatment. The application of the abduction method to them, therefore, is of importance merely in regard to the prevention of the usual deformity, the coxa vara that insures the patient, in spite of the healing of the fracture, more or less total disability from pain and limp.

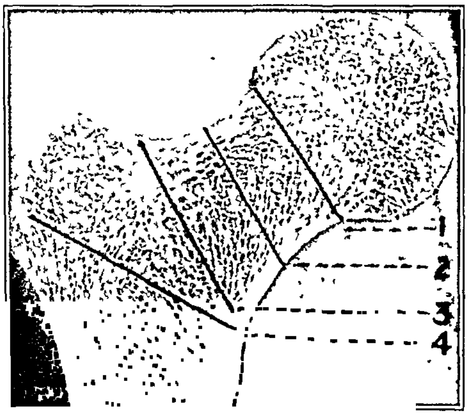

Fig 1.—Fractures of neck of femur: 1, subcapital; 2, transcervical; 3, cervicotrochanteric, 4, pertrochanteric.

The question of the repair of subcapital and transcervical fractures is still unsettled, and opinions vary from that of Delbet, who states that such fractures never unite under any form of treatment, to the statistics of Campbell, who cites 85 per cent of favorable results. But for its extreme importance to the patient this might seem simply a rather exaggerated instance of the usual differences of medical and surgical opinion, and be allowed to pass as such.

I myself should not have believed that such a sharp division of opinion existed in practice as well as in theory had I not recently heard a surgeon of rather extraordinary capability say that he had never seen a case of true subcapital fracture that united by bone Dr. Campbell's statistics, as well as those of Scandinavian, German and French authors, are at his disposal. I assume, therefore, that the evidence that he and others like him crave is cases and not statistics, and I therefore report two cases in my own practice in support of the thesis that subcapital fracture of the neck of the femur may unite under one form of treatment.

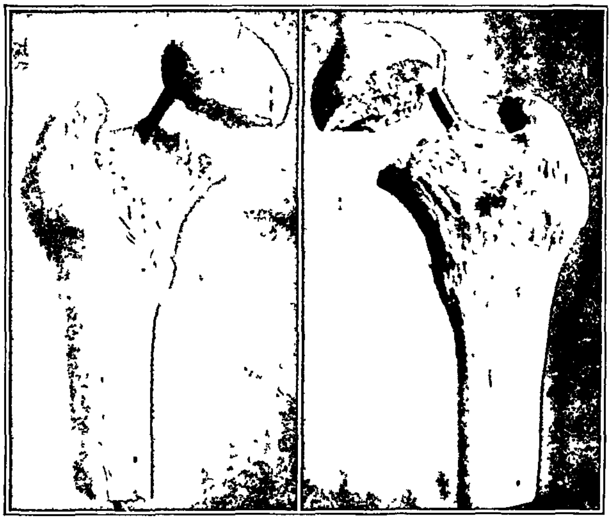

Fig 2 —Absorption of neck following a subcapital fracture. (Specimen 168 from the Musee Dupuytren)

The patient is concerned because, if it be true that such fractures never unite under any form of treatment, the logical course is immediate operation.

In examining the roentgenograms of both these cases, it will be noted that during the course of the immobilization in plaster there has been very considerable absorption of the neck, as illustrated in figure 2, a specimen from the Musée Dupuytren, in spite of which and during and after which, firm, bony union has resulted. This point is of the greatest importance, for two reasons.

The first is that bone grafting operations, nailing or pegging are often advocated for this type of fracture. It will be evident that had a bone graft been inserted in either of these cases its mechanical function could only have been to hold the fragments apart during the process of absorption of the neck exactly in the manner in which the fragments of the specimen in figure 2 are held apart by the metal band, whereas in the abduction method their tendency is to fall ever closer together If union occurs in such a case when a grafting operation has been done, it must be due to the osteogenic power of the graft and to the gradual replacement of the graft by new bone.

[*] From the Hospital for Ruptured and Crippled, First Division

It is conceded that in this type of fracture there is always the possibility of nonunion. Opinions as to percentages of nonunion will probably continue to vary, and most patients will probably continue to prefer the risk of nonunion to the risk of operation.

I take this opportunity to point out that if open operation is ever to be recommended as an immediate remedy for such fractures, bone grafting operations are no more free from the element of risk than the abduction treatment itself. I shall always remember a case in which such an operation was performed by an eminent exponent of the method. At the end of three months the patient was urged to walk, whereupon either the union gave way or the graft broke. The patient shortly after died—some said of disappointment. The only operation free from such an element of risk is the reconstruction operation, which does not depend for its success on the reparative powers of the patient.

REPORT OF CASES

CASE 1.—Mrs. S. S., aged 69, seen, July 30, 1921, slipped and fell, two weeks before, injuring the right hip. She was carried home, put to bed, and had no treatment except advice of her physician to get up and walk and move the limb as much as possible. The patient was in good condition. She was rather obese, lay in bed with the right limb rotated outward, slightly abducted, and was unable to move it voluntarily. Measurements from the anterior superior iliac spine to the internal malleolus were: right, 29½ inches; left, 30 inches. Movements of the limb were not tested because the roentgen-ray examination showed a subcapital fracture of the neck of the femur with very slight displacement.

August 1, under gas and oxygen, the shortening was reduced and the limb abducted to its normal limit, placed in hyperextension and slight inward rotation. A long plaster-of-paris spica holding the limb in this position and the knee in slight flexion was applied.

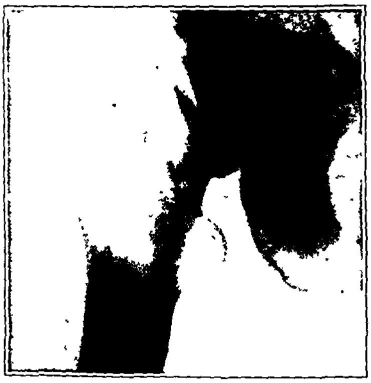

Fig. 3 (Case 1).—Subcapital fracture.

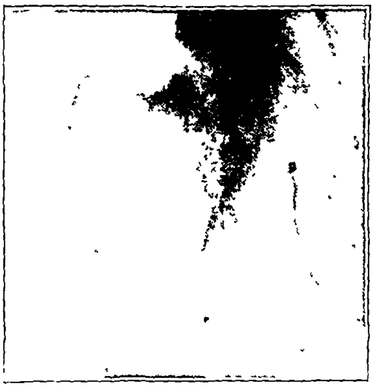

Fig. 4 (Case 1).—Bony union following absorption of half of the neck.

October 15, the plaster was cut away from the posterior aspect of the leg, permitting motion at the knee, which was somewhat limited and painful.

November 1, the plaster was removed entirely. The patient lay in bed. The leg was daily drawn out into full abduction and the patient encouraged to move it. Roentgen-ray examination showed considerable absorption of the neck but apparently firm union.

Jan. 7, 1922, the patient left the hospital, walking with crutches and bearing increasing amounts of weight on the limb.

When last seen at a clinic at the Hospital for Ruptured and Crippled held in November, 1925, the patient walked without a limp. The motions of the hip in all directions were free and painless.

This patient has been shown before the New York Surgical Society as illustrating perfect anatomic and functional recovery following this type of fracture.

CASE 2.—Miss L. G., aged between 50 and 60, at 5 o'clock, Jan. 22, 1925, fell while getting off a Lexington Avenue car. She was unable to rise because of pain and she was brought on a sled half a block and assisted into the house with great difficulty. She was in fair condition. She was rather pale and had an anxious expression. No detailed examination was made because of pain occurring on movement. The right limb was rotated outward at 45 degrees; the knee was slightly flexed; there was apparent very slight shortening. On gentle manipulation, no crepitus was elicited. It was thought that the trochanter was somewhat higher than on the opposite side. Measurements from the anterior superior iliac spine to the internal malleolus were: right, 30 inches, left, 30¼ inches. Roentgen-ray examination showed a typical subcapital fracture of the neck of the femur, the neck displaced upward so that it was on a level with the upper border of the head.

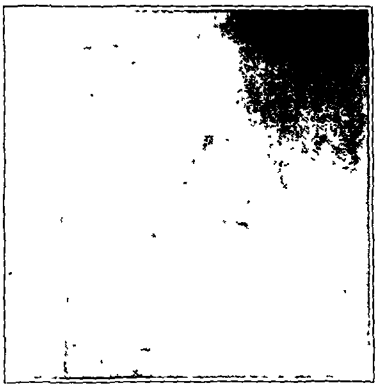

Fig. 5 (Case 2).—Subcapital fracture.

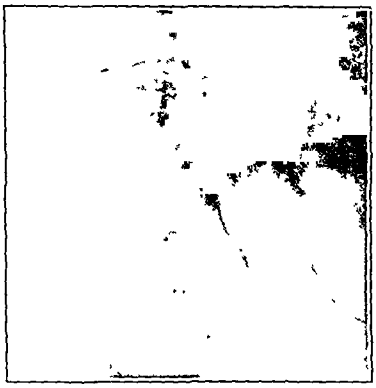

Fig. 6.—Bony union following absorption of the neck.

Under gas, the shortening was overcome and a long plaster-of-paris spica was applied, holding the limb in full abduction, internal rotation and slight hyperextension.

April 20, the plaster was removed. There were a few degrees of motion in all directions at the hip, and apparently firm union.

June 15, the patient left the hospital, walking with the aid of crutches, bearing increasing amounts of weight on the limb.

December 1, the patient was still using crutches on the street because of fear of falling. She was able to make her way about the house with very slight discomfort. She still walked with a slight limp. There was half an inch of shortening, and the extremes of motion at the hip in all directions were somewhat limited and painful. The roentgen ray showed apparently firm bony union.

71 Park Avenue.

Voltaire and Medical Jurisprudence.—There is much to be found in Voltaire's work that will appeal to the medical jurist who is interested in the history of his subject, especially if it be borne in mind that the reform of criminal legislation in France was due to Voltaire (Masmonteil). The trials of Calas, Sirven and Montbailli, the revision of which constitutes the crowning glory of Voltaire, are particularly worthy of study. In both the Calas and the Sirven case, the medical experts appear to have been grossly ignorant and incompetent. —Rolleston, J. D.: *Proc. Roy. Soc. Med.* **19**:89 (Feb.) 1926.

A MICROSCOPIC SLIDE PRECIPITATION TEST FOR SYPHILIS

PRELIMINARY REPORT *

B. S. KLINE, M.D.
AND
A. M. YOUNG, A.B.
CLEVELAND

Our purpose in this report is to describe a microscopic slide precipitation test for syphilis with Kahn's antigen which is as sensitive as the routine three tube Kahn test with the following advantages over that method: 1. It is simpler. 2. It requires less apparatus and much less serum. 3. The results are easier to read.

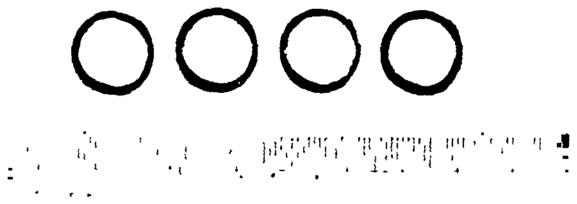

Fig. 1.—Microscopic slide with paraffin rings, slightly reduced.

Since the publication of the first precipitation test for syphilis by Michaelis,[1] in 1907, numerous modifications of antigen and technic have been suggested, especially by Porges and Meier,[2] Bruck and Hidaka,[3] Herman and Perutz,[4] Meinicke,[5] Sachs and Georgi,[6] Dreyer and Ward,[7] Vernes [8] and Kahn.[9] Of these, the Kahn test has apparently received the widest acceptance, giving results, in the hands of numerous workers, in close agreement with the Wassermann test and with the clinical findings.

In commencing work with the Kahn test in this laboratory, we were greatly assisted with the technic by Dr. Kahn, who not only supplied us with antigens and details concerning his method but also gave Miss A. B. Mill of our staff an opportunity of following the work in his own laboratory. In a subsequent communication with Miss Mill we hope to report a large number of parallel Kahn and Wassermann tests. The parallel Kahn and Wassermann tests thus far performed by her (table 4) agree closely.

The Kahn three tube precipitation test, although easy to perform, is somewhat difficult to read without considerable practice and requires 0.45 cc. of serum. Because of the fact that sufficient quantities of serum are not always obtainable or available, some attention has been given to the development of a precipitation test requiring comparatively small quantities of serum. In one of Kahn's publications,[10] there is a record of a micromethod tried by him "with the hope," he states, that it may prove helpful in those cases in which regular quantities of serum are not available. Hanging drop preparations were prepared with minute amounts of serum measured with a capillary pipet and approximately one sixth the amount of antigen measured with a pipet of similar size, employing the usual procedure. After given periods of incubation, the positive serums showed under the microscope clumps of minute globules, whereas in the case of negative serums the mixture appeared homogeneous.

It was observed, however, that this method gave considerably weaker results than the regular one, large numbers of weak serums giving no precipitation reactions with these microscopic quantities. This was found to be due, not to the relatively minute serum and antigen quantities, but to improper agitation of these two substances. For successful precipitation reactions, the serum and antigen must be thoroughly mixed. We have therefore found it more dependable to employ small agglutination tubes for this microprocedure and thus to enable proper mixing of the serum and antigen by shaking.

Another precipitation test (a modification of the Sachs and Georgi test) requiring small quantities of serum was reported by Priestley [11] in 1923. The following is an extract of his technic employing comparatively large plates:

> The slide is 29 by 5 cm., cut with a diamond into twenty compartments; this allows of four sera with their serum controls being tested in four dilutions at the same time. Those sera which were positive in these dilutions were then put up in higher dilutions to extinction of precipitation. For the volumes of serum dilutions and antigen, pipets of no. 52 Starrett wire gage were used, one being kept for the serum dilutions and one for the antigen dilution. The sera were put up in dilutions of 1 in 2½, 1 in 5, 1 in 10, 1 in 20, etc., and one drop of antigen dilution added to each except the serum control, which consisted of one drop of neat serum and one drop of saline. Rotation of the slide, either by hand or by means of a clockwork device similar to Garrow's over an angle of 45 degrees on either side of the horizontal, was carried on for five minutes, when the results were read by a watchmaker's lens, and expressed as one, two or three plus according to the size of the flocculi. The antigen used has been a mixture of alcoholic human heart extract and 1 per cent alcoholic cholesterol in the proportion of 3 to 2 parts. The same antigen has been used throughout the Wassermann reaction tests, but in a different dilution. Bordet's antigen plus cholesterol was tried, but appeared to give no better results than the crude heart extract. A dilution of 1 in 5 appeared to give the best results, the antigen being measured into a dry tube and the salt solution slowly dropped into it from a height of 12 inches. Of 500 parallel tests a superficial examination shows agreement in 395 (79 per cent) and disagreement in 105 (21 per cent); and of the latter the Wassermann reaction yields stronger results than the slide

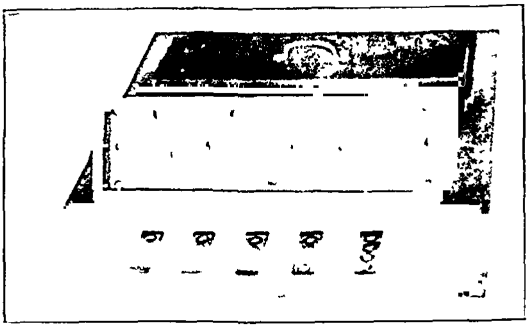

Fig. 2.—Humidor cover for incubating slides (two views), greatly reduced.

Sachs-Georgi in sixty-one (12.2 per cent), and the Sachs and Georgi than the Wassermann reaction in forty-four (8.8 per cent).

Although the open microscopic slide method of agglutination has been widely adopted for blood typings and bacterial agglutinations since the publication of Vincent's article,[12] we have found no reference in the literature to the use of microscopic slides in precipitation tests for syphilis.

After we had done the Kahn three tube test a few times, it was decided to run as a simple control a microscopic slide test with a technic employed in this laboratory for blood typings and bacterial agglutinations. In spite of various dilutions, the microscopic slide method has agreed closely with routine Kahn and Wassermann tests (tables 1, 2 and 3). In addition to the parallel tests recorded in the tables, many more microscopic slide tests were performed with the purpose of establishing a satisfactory routine procedure. As a result of various modifications tried in 527 tests, the following technic, because of its simple requirements, ease of performance and apparent specificity, is recommended for trial.

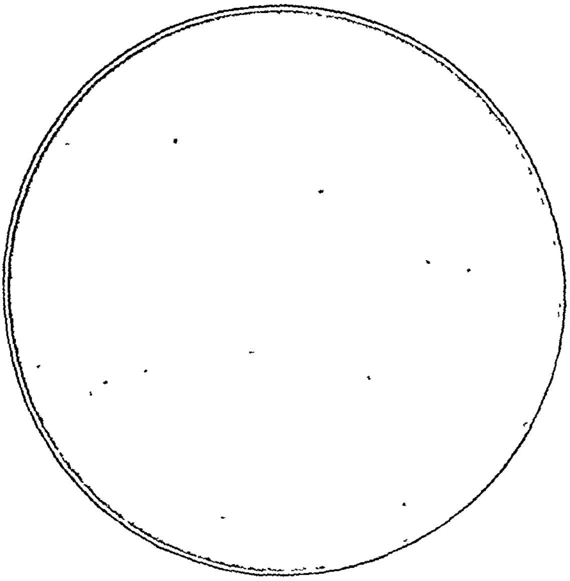

Fig. 3.—Negative slide test (through 16 mm. objective, 12.5 eyepiece).

MICROSCOPIC SLIDE PRECIPITATION TEST

Glassware and Apparatus.—Ordinary microscopic slides are washed in soap and water, rinsed thoroughly in water, allowed to remain in 95 per cent alcohol for a short time, dried and then flamed. After this, four paraffin rings (each with an inside diameter of 11 to 12 mm.) are made on one surface according to the method of Green[13] by transferring a small amount of hot paraffin on a stiff wire (gage 19) wound with thread (or hat wire) bent to the form of a circle (fig. 1).

The pipets needed for delivering the serums are the ordinary 1 cc. pipets graduated in 0.01 cc. The pipets for the antigen are the same as those for the serums with the ends drawn out so that each drop of antigen dilution equals 0.015 cc. The diameter of the tip over all is about 1.25 mm.

Vials for preparing the antigen dilution are similar to those used and recommended by Kahn.

A humidor cover is necessary for the test. The one employed in this laboratory consists of a wooden lid, 16½ by 4 by 1½ inches inside diameter, with a moistened blotter fastened in place with thumb tacks, as shown in figure 2.

Antigen.—The antigen and antigen dilution are prepared as for the Kahn test. The antigen titration likewise is done as for the Kahn test. The antigen dilution should be made up just before pipetting the serums. Some antigen dilutions have been found to work only within fifteen minutes of their preparation. An average antigen dilution may still be used forty-five minutes after its preparation.

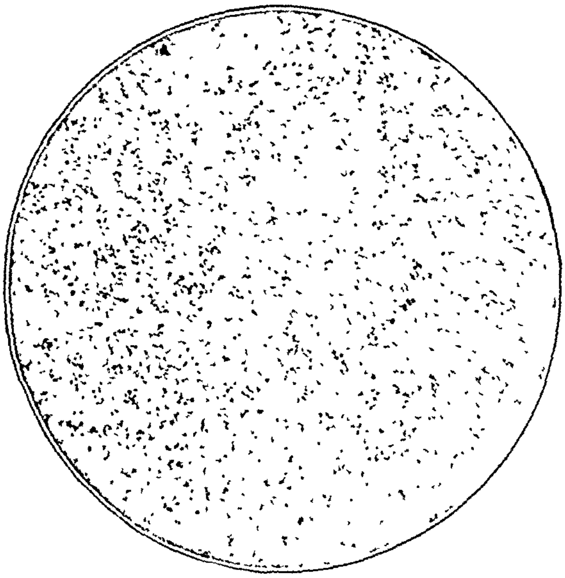

Fig. 4.—Slide test + (through 16 mm. objective, 12.5 eyepiece).

The action of the antigen dilution has been found unsatisfactory when the room temperature and that of the microscopic slides is low; again, false clumping occurs in serum antigen dilution mixtures allowed to dry. Accordingly, it is important to do the test in a warm, humid room (about 80 F. with visible moisture on the windows), which is readily prepared by heating a pan of water after closing the windows and doors. The table top on which the tests are performed should be kept warm. A piece of harness felt three-fourths inch thick is satisfactory for this purpose.

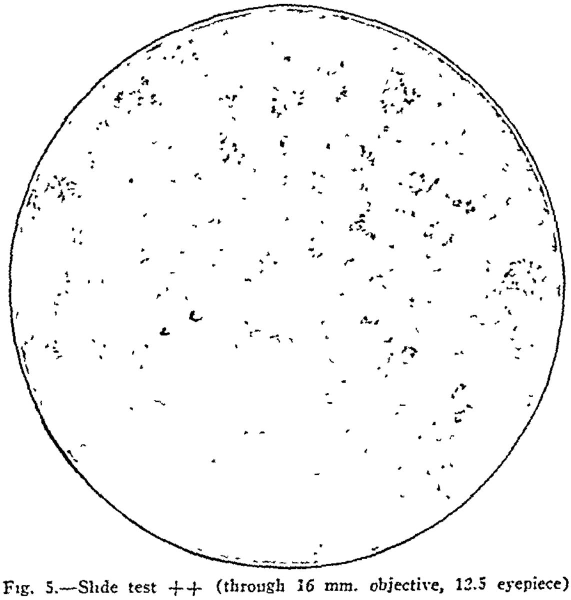

Fig. 5.—Slide test ++ (through 16 mm. objective, 12.5 eyepiece).

Serums.—These are obtained as for the Wassermann test, care being exercised that they contain no red blood cells or foreign material. Before use, they are heated to 56 C. for one-half hour.

---

[12] Vincent, Beth: A Rapid Macroscopic Agglutination Test for Blood Groups, and Its Value in Testing Donors for Transfusion, J. A. M. A. **70**: 1219 (April 27) 1918.

[13] Green, G.: Am. J. Pub. Health **15**: 651, 1925.

The Test.—Into each ring, 0.06 cc. of the undiluted serum to be tested is delivered from a pipet. It is advisable to work with not more than twelve serums (three slides) at a time. After all the serums are pipetted, 1 drop of Kahn's antigen dilution (0.015 cc.) is allowed to fall into the serum in each ring. After all the antigen is pipetted, the small amount in each ring is evenly distributed by rapidly stirring the mixture with a tooth pick (a new tooth pick with flat end a few millimeters in width is used for each test). After the mixtures are complete, the slides, without further agitation, are placed below the humidor cover and allowed to remain at room temperature for ten minutes. At the expiration of this time, the first slide is removed, rocked and rotated by hand for about sixty seconds (about sixty times) and read immediately. The readings are made through the microscope (16 mm. objective, 10 or 12.5 eyepiece) with the light cut down as in studying urinary sediments and recorded in terms of pluses according to the size of the clumps, as shown in figures 3 to 7. Because of the importance of the test, it is strongly recommended that it be done in duplicate, different antigens being used.

In performing the tests, capillary pipets (drawn from glass tubing) with bulbs holding about 10 drops of fluid may be used instead of those described.

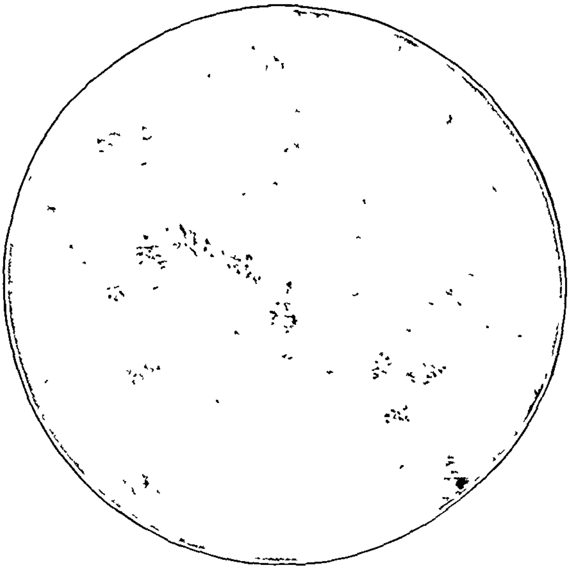

Fig 6.—Slide test + + + (through 16 mm objective, 12.5 eyepiece).

COMMENT

The test as described is recommended as the one yielding the best results of the numerous procedures employed in 527 tests, included among which were tests with varying quantities of serum (from 0.01 to 0.06 cc.), antigen dilution (from 0.0075 to 0.03 cc.) rings of various sizes (from 8 to 13 mm.) and incubation periods of various lengths (from five to forty-five minutes) in the open air and in the humidor. The antigens used have been Kahn's standard and special antigens kindly furnished by Dr. Kahn, and also similar antigens prepared according to his formulas.

It should be remarked at this point that the open slide method described above is ideal for the mixture of serum and antigen, contrasting with the hanging drop method tried by Kahn. At the same time, however, the larger surface offers greater opportunity for rapid drying, and, unless this is prevented, false clumping may occur. This danger is completely obviated by incubating the test below the humidor cover.

In the performance of the test by the method recommended, it has been observed that the strongly positive serums require no agitation beyond the initial stirring with a tooth pick, the clumping being almost immediate. The rocking and rotation, however, accentuate the

clumping not only in the weakly positive but also in the strongly positive serums.

It has been found that a considerable range in the quantities of serum and antigen can be employed with success. The quantities recommended, however, have been found the most satisfactory.

When compared with the routine Kahn test, the microscope slide test will be found much simpler, requiring less apparatus and for a single test but one-seventh the amount of serum. Perhaps the greatest advantage is the greater ease of reading the results. The completed test is easily viewed through the microscope, and the results, appearing as in the accompanying illustrations, are much more striking than those of the Kahn test.

The test should be of particular value when only small quantities of serum are obtainable and when, as in emergency blood transfusions, prompt knowledge of the presence or absence of syphilis in the donor is desirable.

Comparative results of microscopic slide precipitation tests as described, Kahn tests, and Wassermann tests are given in the tables.

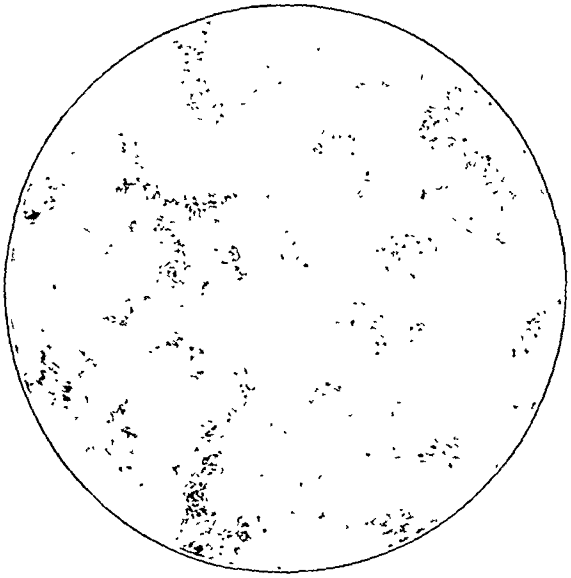

Fig. 7.—Slide test ++++ (through 16 mm. objective, 12.5 eyepiece).

As will be seen from the tables, there is a close agreement between the microscopic slide precipitation test, the Kahn test and the Wassermann test.

CONCLUSION

The microscopic slide precipitation test for syphilis with Kahn's antigen described in this report is as sensitive as the routine three tube Kahn test and has the following advantages over that method: 1. It is simpler. 2. It requires less apparatus and much less serum. 3. The results are easier to read.

Insomnia a Bad Habit.—Insomnia or sleeplessness is, in most instances, a bad health habit that can be cured without an undue expenditure of effort, if the will is present to conquer it. There is no great danger in staying awake at night if the wakefulness is not caused by actual pain, disease, infection, or a necessity which permits of no relaxation for long hours.—Wood, T. D., and Dansdill, T.: By-Ways to Health, 1925, p. 88.

MASSIVE INTRAPERITONEAL HEMORRHAGE

FROM A RUPTURED PAPILLARY ADENOCYSTOMA OF THE OVARY

LOUIS E. PHANEUF, M.D.
BOSTON

In 1924, I[1] had the opportunity of looking up the subject of intraperitoneal hemorrhage of ovarian origin. In reviewing the literature from 1900 to 1924, I found no mention of the rupture of a papillary adenocystoma of the ovary as the specific cause of a massive hemorrhage. These growths are usually multilocular, and are commonly associated with free fluid in the abdominal cavity and with secondary peritoneal involvement, although ascites may be absent as long as the papillary masses remain within the cyst cavity. On perforation of the cyst, the papillary growths spread over the surface of the neoplasm, and invade the uterine and pelvic peritoneum, and finally the parietal peritoneum and that covering the abdominal organs. Extensive involvement of the peritoneal cavity is looked on as a malignant condition, although this is not always so, since the secondary peritoneal masses have been known to disappear following the removal of the original cyst.

A case of life-endangering bleeding from such a cyst came to my attention in May, 1924, and forms the basis of this report.

REPORT OF CASE

History.—Mrs. S. L., aged 66, was seen in consultation at her home, May 10, 1925, and was admitted to the Carney Hospital gynecologic service on the same date. Her complaints were pain in the abdomen, abdominal distention, and constipation of two days' duration. Her father had died of an accident; her mother, of cancer of the stomach, at the age of 79; one brother, of pneumonia, at 54 years of age (ten years previously); one sister, of cerebral hemorrhage, at 57 years of age (nine years previously). Two sisters and one brother were living and well; there were no chronic diseases in the family. The patient had influenza and bronchopneumonia in 1918, and she had a trachelorrhaphy performed eighteen years previously. Menstruation was established when she was 15; the periods were regular, of the twenty-eight day type, and lasted from four to five days, without pain. She had reached the menopause fourteen years before admission, and had had no vaginal bleeding since. The patient had been married forty-one years; her husband was living and well, and she had five living children, the oldest being 38 and the youngest 27. She lost one child at the age of 6 months, the cause of death being given as convulsions. Her first three deliveries were instrumental; the others were normal. The puerperia were normal. Three months before I saw her, the patient felt a mass in the abdomen, which she described as floating, especially when she changed her position. There was no distinct pain or discomfort until the day before admission, when she began to complain of gas pains, accompanied by progressively increasing distention. At this time she began to have a bloody vaginal discharge. She was given an enema at home, but this was not effectual and did not relieve the distention or the pain, which seemed to be general in the abdomen. The history was otherwise negative.

Examination.—The patient was emaciated, in a state of shock, had an anxious expression, and was apparently suffering a great deal of pain; the respirations and pulse rate were increased, and she was anemic in appearance. The head, lungs and heart were normal.

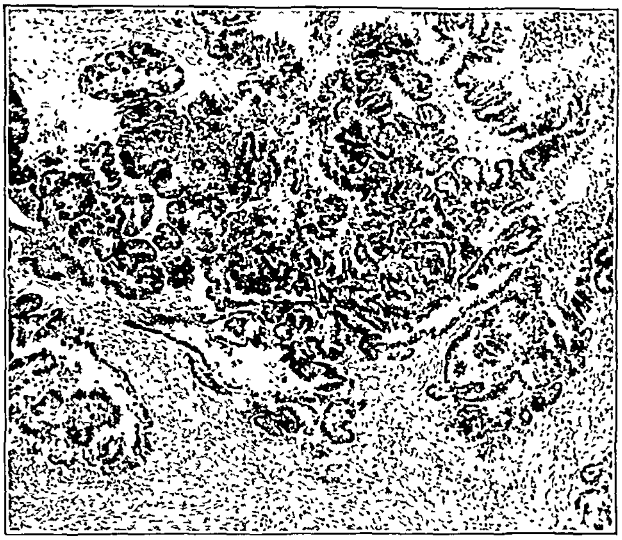
The abdominal examination showed marked distention and extreme rigidity; the abdomen was tympanitic in the center, but dull in the flanks. The distention was symmetrical, and palpation suggested a mass which was probably connected with the uterus. There was so much pain on palpation that this was not satisfactory. There was marked spasm of both rectus muscles.

---

[1] Phaneuf, L. E.: Intraperitoneal Hemorrhage from Ruptured Ovarian Cyst, J. A. M. A. 83: 658-662 (Aug. 30) 1924.

The vaginal examination revealed a large mass filling the pelvis, and probably having its origin on the right side of the uterus. The culdesac of Douglas was bulging, and probably contained fluid. There was a bloody vaginal discharge. The pelvic examination was unsatisfactory, because of the pain elicited in the attempt to differentiate the pelvic organs.

Operation.—May 10, under ether anesthesia, a median abdominal incision was made from the symphysis to the umbilicus. When the abdomen was opened there was a gush of fresh blood. The abdomen contained about 2 liters of fluid and clotted blood. The pelvic peritoneum and the small and large intestines were markedly distended, and were covered with numerous white tubercles suggesting malignant disease. On the right of the pelvis, a large ovarian cyst covered with papillary projections was found; this had ruptured and blood clot filled the rent. The pedicle was clamped and tied, the cyst was removed, and the blood was evacuated. The uterus, the left adnexa and the right tube were also covered with papillary masses. The abdomen was quickly closed in layers, and the patient left the operating room in fairly good condition.



Papillary adenocystoma of ovary; × 100.

Convalescence.—The patient made a good ether recovery; she had some nausea and vomiting, and complained of pain in the region of the incision. The pulse was of fairly good quality. The distention had decreased the day after operation; the pain was much less; the temperature was 100.4, and the pulse 100. The patient was given physostigmin sulphate, $\frac{1}{50}$ grain (1.3 mg.) hypodermically every four hours for four doses, and was given glucose solution, 250 c.c., every four hours by rectum. May 16, she felt weak; the distention was under control; the temperature was 101.8; the pulse was 120; there was no pain or vomiting, and the patient was thirsty and was taking fluids by mouth freely. The skin was cold at times. May 19, the sutures were removed; the incision had healed by first intention; there was no induration or tenderness of the incision. May 23, the patient felt well; the pulse, temperature and respirations were normal. May 28, the seventeenth postoperative day, the patient was allowed out of bed, and she was discharged on June 1, at which time the incision was dry and well healed; there was no induration or tenderness, and the temperature and pulse were normal. The vaginal examination showed a small uterus in second degree retroversion; the lateral vaults were clear, and there was no pelvic tenderness.

Pathologic Report.—Examination of the specimen was made by Dr. F. B. Mallory. It consisted of a collapsed cystic tumor mass which measured about 20 by 10 by 5 cm., with many cysts filled with fluid and papillary outgrowths from the walls. In places it showed extensive necrosis. Microscopically, the tumor consisted of papillary branching stalks of vascular connective tissue covered with a layer of cylindric cells, as shown in the accompanying illustration. The diagnosis was typical papillary adenocystoma of the ovary.

Subsequent Notes.—June 20, the patient, who had gone to Brooklyn, reported that she was convalescing satisfactorily, was free from pain, and was out every day. July 7, her husband stated that she was comfortable in every way except for a certain amount of gaseous eructations after meals, but he asserted that she had been subject to those for a number of years. August 1, the patient reported that she continued to improve, went out shopping alone daily, had gained 1 pound (0.5 kg.) in the previous three weeks, was eating and sleeping well, and was generally doing well.

COMMENT

When this patient was first seen, the clinical picture was that of an ovarian tumor, ascites, and intestinal obstruction. A severe hemorrhage was not suspected. The state of shock was ascribed to the obstruction, while the anemic condition of the patient was thought to be due to malignancy and cachexia. She made a surprisingly good recovery, and her constant improvement since operation gives the hope that she may be classed in the group of cases in which the secondary peritoneal involvement disappears after the removal of the primary tumor.

395 Commonwealth Avenue.

MEASLES TOXIN

ITS PREPARATION AND APPLICATION AS A SKIN TEST, AS AN IMMUNIZING AGENT, AND FOR THE PRODUCTION OF AN ANTITOXIN *

N. S. FERRY, M.D.
AND
L. W. FISHER, B.S.
DETROIT

This is a preliminary report of the preparation of measles toxin from a micro-organism isolated by us in pure culture from the blood of patients in the early stages of the disease.

The micro-organism is characterized as a small, gram-positive, aerobic, green producing streptococcus, appearing both in pairs and in chains, which produces an extracellular or soluble toxin specific to measles.

In obtaining this organism, about 10 cc. of blood, drawn directly from the median cephalic vein, was planted in 0.25 liter flasks of Hibler medium, incubated twenty-four hours and plated directly on sheep blood agar. The plates were incubated aerobically twenty-four hours and planted from that to blood agar slants or into 0.2 per cent glucose broth.

The organism we have isolated differs from that described by Tunnicliff, in that it is an aerobe growing luxuriantly in the presence of oxygen and that it produces a soluble toxin specific to measles.

In order to distinguish the streptococcus isolated by us from any organism previously described, as so many have been found in the blood of measles patients, we have called it *Streptococcus morbilli.*

---

* From the Medical Research Laboratories, Parke, Davis & Co.

* This work was made possible through the courtesy of Dr. Henry F. Vaughan, commissioner of health, the officers of Herman Kiefer Hospital, and especially through the assistance of Dr. B. B. Bernbaum and Dr. E. Martmer of Herman Kiefer Hospital and Dr. R. W. Pryer, director of the board of health laboratories, Detroit.

In the preparation of measles toxin, the streptococcus in question was planted in 1 liter flasks of 0.2 per cent glucose broth and incubated six days, the flasks being agitated every twenty-four hours. A luxuriant growth resulted which, on passing through a Berkefeld W candle, gave a toxin of the strength of 5,000 skin test doses per cubic centimeter. To the toxin, 0.5 per cent phenol (carbolic acid) was added as a preservative.

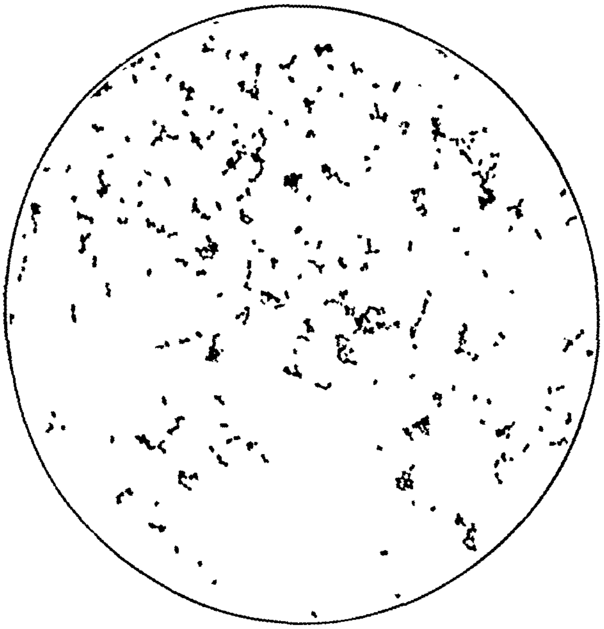


Fig. 1.—Appearance of organism as grown on solid medium.

Proof of the presence of toxin in broth filtrates of our organism, evidence of the specific relationship of this toxin to the disease, and proof of the etiologic relationship to measles of the organism from which it was obtained are shown in the experiments reported here. These experiments were carried out on persons susceptible and those immune to measles, as well as on persons suffering with the disease; also on rabbits and other animals.

1. Persons with no histories of measles gave positive skin reactions, on intracutaneous injections of 0.1 cc. of a 1 : 500 dilution of the toxin, showing that they were sensitive to the toxin. Out of thirty-five tests on persons giving negative histories, fourteen gave positive skin reactions to intracutaneous injections of the toxin.

In carrying out the skin test, 0.1 cc. of the toxin was injected intracutaneously, according to a technic similar to that for the Schick or Dick test, and a reaction 1 cm. or more in diameter was considered positive. All tests were controlled by injecting on the other arm toxin heated for one hour at boiling temperature or neutralized with convalescent serum. Measles antitoxin obtained from an animal immunized with the toxin was also used as a control. Readings were taken at the end of twenty-four or forty-eight hours.

In some instances, false control reactions were encountered when persons were sensitive to the serum used as a neutralizing medium.

2. Persons giving positive histories of measles did not react to intracutaneous injections of the toxin.

Thirty children were tested and in no instance was a positive test recorded. Two adults out of thirty, however, with positive histories have so far reacted positively.

3. Patients in the preeruptive and early stages of the disease gave positive skin reactions to the toxin, while those in the later stages, and especially convalescents, gave negative skin reactions.

In hospital practice it is almost impossible to find a case of measles in the preeruptive stage, but out of fifteen cases obtained as early as possible, seven gave positive reactions and none of the late and convalescent cases, twenty-four in all, reacted to the toxin.

4. When mixed with measles convalescent serum, the toxin will not produce a positive skin reaction in susceptible persons, showing that the convalescent serum neutralizes the toxin. Many of the controls were prepared by mixing measles convalescent serum with the toxin, and in most instances the reaction was negative.

5. When mixed with serum from an animal immunized with the toxin, in other words an artificially prepared antitoxin, the toxin will not produce a positive skin reaction in susceptible persons. This shows that this toxin is capable of stimulating the production of an antitoxin and that this antitoxin has the same neutralizing properties for this toxin as has measles convalescent serum.

This test was carried out on twelve susceptible persons, and in every instance the toxin was neutralized by the antitoxin to such a degree that there was no sign of a reaction on the control arm.

6. When mixed with scarlet fever antitoxin or normal horse serum, the toxin was not neutralized.

Control tests were positive when we used scarlet fever antitoxin and normal horse serum, showing that these serums did not neutralize the toxin.

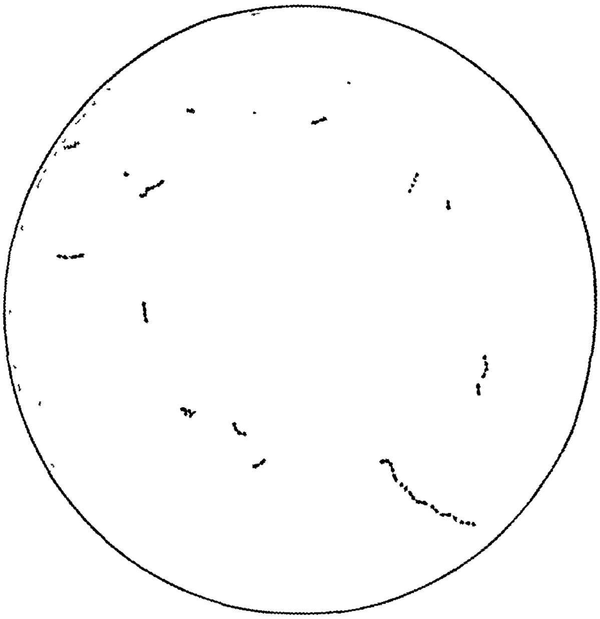

Fig. 2.—Appearance of organism as grown in broth medium.

7. Persons giving positive reactions to intracutaneous injections of the toxin are made to give negative reactions by subcutaneous injections of measles convalescent serum.

Two out of four persons showing positive skin reactions were given 10 cc. of convalescent serum, and after two days all four were retested. The two who received the serum gave negative tests, while the two controls were still positive. This test was carried out by Dr. Martmer of the Herman Kiefer Hospital.

8. A person giving a positive reaction to the skin test was made to show a negative reaction by the subcutaneous injection of the serum of an animal immunized with the toxin, showing that an antitoxin artificially prepared has the same immunizing or neutralizing properties for this toxin as has the serum from a person naturally immune. This is strong evidence of the etiologic relationship of the toxin and streptococcus in question to the disease.

This test was carried out on but one person, but the result was so striking that it was felt that it should be reported.

9. Serum of measles convalescent patients agglutinates suspensions of our measles streptococcus, while negative serum does not.

The serum was from a lot which had been pooled from several convalescent serums obtained from Herman Kiefer Hospital.

Four strains of the measles streptococcus were agglutinated against this serum, and two out of the four reacted.

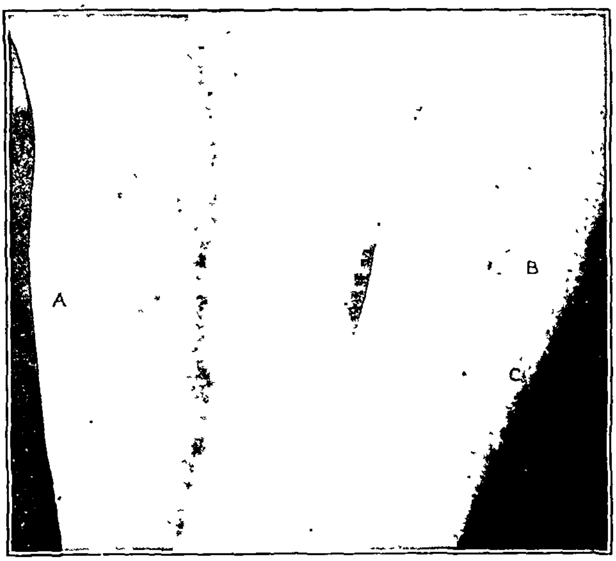

Fig. 3.—Cutaneous reaction with measles toxin: *A*, measles toxin alone; *b*, measles toxin neutralized with measles convalescent serum; *C*, measles toxin neutralized with measles antitoxin.

10. Intracutaneous injections into rabbits of live cultures of our organism produced severe local infections surrounded by large areas of hyperemia, which at times extended over the entire abdomen and back, appearing very much as a typical measles rash.

About 0.1 cc. of broth culture was injected intracutaneously, and within two days there appeared a large raised area, about 4 cm. in diameter, which next day resulted in an abscess with sloughing. One rabbit showed a distinct redness over the entire abdomen and back, while others were more or less hyperemic.

11. Intracutaneous injections of killed cultures of this organism into the rabbit produces at the site of injection a large local reaction not unlike the reaction following the injection of the live organism into the rabbit and the toxin into the human subject.

In every instance, rabbits injected intracutaneously with killed broth culture of the organism showed a reaction about the size of a quarter with, in some instances, a small sterile abscess in the center.

12. Animals injected with the measles toxin will produce serums with antitoxic properties, showing that the toxin is a true extracellular or soluble toxin.

Horses and rabbits were injected subcutaneously with the specific toxin, in a manner similar to the production of other well known antitoxins, and proof of the antitoxic properties of the serum from these animals was evidenced by its ability to neutralize the toxin both in vivo and in vitro.

PHRENIC NERVE INJURY IN THE NEW-BORN

REPORT OF CASE *

EMANUEL FRIEDMAN, M.D.
AND
R. S. CHAMBERLAIN, M.D.
DENVER

In 1921, Kofferath [1] reported a case of diaphragmatic paralysis resulting from injury to the phrenic nerve in association with an injury to the brachial plexus. The paralysis of the diaphragm was discovered shortly after birth, and that of the arm twenty-four hours later. Kofferath was unable to find a single reference to this complication detected immediately after delivery. Ehrenfest,[2] in commenting on this unusual complication, observes that Weigert had collected records of thirty cases including one of his own, and that Kofferath's was the only one in which the diagnosis had been verified by fluoroscopic evidence. Reference to Weigert's [3] original article, bearing the caption "Relaxatio diaphragmatica," makes it manifest that he includes related pathologic conditions. His own case bears the earmarks of diaphragmatic paralysis due to phrenic nerve injury; however, whether sustained at birth or not is not quite apparent. From his discussion we are permitted to gather that some of the included cases undoubtedly represent instances of hernia of the diaphragm permitting the escape of the stomach or the bowels into, usually, the left pleural space; and others, of a poorly developed or rudimentary septum, allowing some abdominal viscera to be crowded into the left thoracic cavity. Of the thirty cases, only two concerned the new-born and two more were found in later infancy.

We have made a diligent search of the available literature and standard textbooks and have failed to find any other record of phrenic nerve injury supervening at birth in connection with or independent of a lesion of the brachial plexus. Apart from Ehrenfest, who quotes extensively Kofferath's article, and Finkelstein,[4] who disposes of the subject with a brief reference to the same publication and to the possibility of such occurrence during labor, no others mention this particular complication.

That this cannot be so unusual an occurrence may justifiably be deduced when we take into account the intimate anatomic relationship of this nerve to the brachial plexus. It is a reasonable assumption that any serious injury to the upper cord of this plexus is quite likely to involve in some measure the filaments that make up the phrenic nerve. Kofferath likewise expresses the belief that this type of injury is not very rare. It is almost invariably overlooked, because the most prominent symptom it gives rise to is common to numerous pathologic conditions frequently encountered in the new-born.

---

CAUSATION AND SYMPTOMS

Kofferath, by implication, conveys the thought that injury to the phrenic nerve may take place without concurrent harm to the plexus. It is our impression that injury to the nerve innervating the diaphragm will be found far more frequently in association with Erb's palsy than as an isolated phenomenon. It is doubtless brought about under the same circumstances and by the operation of the same forces that eventuate in an upper arm paralysis.

An associated involvement of the brachial plexus will of course be made manifest by an upper arm palsy. The result of injury to the phrenic nerve is paralysis of the diaphragm, betrayed principally by disturbances in respiration. Because these and the associated changes are so accurately detailed by Kofferath, and because no other description of this accident in the new-born is available, I shall recount his findings rather minutely. He noticed that soon after birth the respirations were labored as if some obstruction were present in the upper respiratory tract, and the breathing was thoracic in type. The character of the breathing and evidence of injury inflicted by the forceps at Erb's point on the right side suggested the possibility of traumatic phrenic paralysis. The right brachial arm palsy had not appeared until the following day. The fluoroscopic examination confirmed his suspicions by revealing a classic Kienböck phenomenon, so designated since 1898. The right part of the diaphragm occupied an abnormally high position. Inspiration was accompanied by an ascent of this part of the diaphragm and expiration by a descent, the very reverse of what takes place normally. The left side of the diaphragm behaved in the usual manner. In other words, when the right ascended the left simultaneously descended, and vice versa. Furthermore, the right half of the liver moved in unison with the right half of the diaphragm, and the left lobe synchronously with the corresponding half of the diaphragm. During inspiration the heart was pushed toward the left and downward. The mediastinum showed no widening. The liver was not palpable. By the fourth day, the breathing had resumed its normal type, and there was distinct decrease in the arm paralysis. Three months after birth, the child's respirations and its general behavior were normal. At the age of 4 months, the right part of the diaphragm was still a little higher than its fellow, and aside from increased density the lung showed no abnormality. The two portions of the diaphragm moved in the same direction. The right arm showed no weakness. Labor had presented no unusual features, and was not regarded as difficult.

Symptoms are modified when the paralysis occurs on the left side, allowing the stomach or even the intestines to displace the contents of the left thoracic cavity. Such conditions prevailed in Weigert's case. The cough was distressing, respirations seriously hampered, and digestive symptoms were prominently in the foreground. Physical examination at first suggested rightsided pneumonia, but the frequently changing signs on the left side suggested the existence of diaphragmatic hernia; this was confirmed by the roentgen ray. The patient was in a critical condition for six weeks, when slight abatement in the symptoms took place. Improvement thereafter was progressive, and at 1 year of age the child was quite well and all the viscera were found in their normal position.

When injury to the nerve is slight, symptoms may be mild and transitory and therefore not likely to excite attention.

DIFFERENTIAL DIAGNOSIS

A diagnosis of phrenic nerve injury can be made with certainty only by the roentgen ray. The same agency will likewise disclose nearly all the pathologic conditions from which diaphragmatic paralysis is to be differentiated. Clinically, pneumonia is usually characterized by high fever and leukocytosis; enlarged thymus, by stridor; pneumothorax, by unilateral hyperresonance; cerebral injury, by abnormal spinal fluid; atelectasis, by bilateral feebleness of the vesicular murmur; diaphragmatic hernia, by changing physical signs and displacement of the heart, and congenital heart lesion by a pronounced murmur.

PROGNOSIS

Return of function of an injured phrenic nerve is more gradual than of the arm, and even in mild injuries, is probably not complete for several months. If the injury is severe, permanent paralysis may follow. During the height of the paralysis, because of defective pulmonary ventilation, one would anticipate an increased liability to respiratory infections. If both phrenic nerves are injured, the outlook is exceedingly grave.

PROPHYLAXIS AND TREATMENT

The high incidence of all birth injuries may be appreciably reduced by refraining from injudicious intervention with the progress of labor, and by the exercise of greater care in the execution of necessary manual and instrumental manipulations.

Restitution of function to the injured phrenic nerve will be materially assisted and hastened by appropriate treatment of the injured arm. The laissez-faire attitude of the past is no longer tenable. The cooperation of the orthropedic surgeon should be sought; with the aid of suitable appliances, massage, passive movements and electricity, better results will be insured than heretofore. For the relief of dyspnea, oxygen and appropriate cardiac and respiratory stimulants may be indicated. Nutrition must be carefully maintained and the child sedulously guarded against all infections, particularly of the respiratory type, because the supervention of these would almost certainly end disastrously.

REPORT OF CASE

Our justification for recording the case reported here rests on the conviction that it represents in all probability a not very uncommon birth complication. When the possibility of its occurrence is once appreciated, its discovery is accomplished with ease and certainty. In less than four months after the patient under consideration came to our notice, one of us promptly recognized in consultation another, presenting features almost identical with those here recorded.

History.—S., a girl, seen, Feb. 24, 1925, at the age of 7 days, by courtesy of Dr. S. G. Phillips, was the first born of young healthy parents; labor was not prolonged and was assisted by the application of low forceps. It was estimated that birth was delayed one month beyond term, because of hydramnios. The presentation was vertex, in left occipito-anterior position. The baby weighed 6½ pounds (2.9 Kg.) at birth, and no deformities were noted. The breathing showed no change from the normal, and the cry was vigorous and clear.

Soon after birth, it was discovered that the right arm was motionless. Within twenty-four hours, paralysis of the arm had appreciably decreased. The nurse in attendance had observed during brief periods, at irregular intervals, attacks of mild cyanosis during the first few days of life. These were not considered of serious import. The baby nursed well, did not vomit, and the stools were normal. Its behavior and appearance, apart from the arm palsy and the fleeting attacks of cyanosis, were considered normal in all respects.

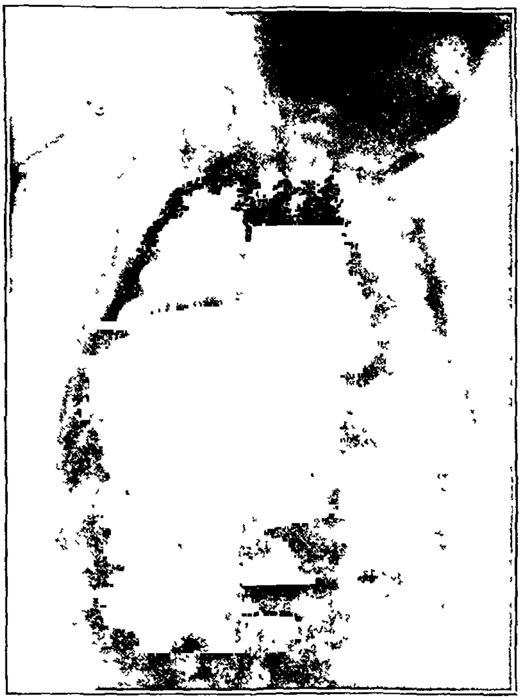

Fig 1.—Abnormally high right side of diaphragm due to paralysis of phrenic nerve, seventeen days after birth

At the age of 7 days, the infant was well nourished and normally developed, weighing approximately 7 pounds (3.2 Kg.) Its cry was clear and lusty. Turgor of the skin and muscles was good There were no external evidences of injury. Cyanosis was not present. The visible mucous membranes showed good color. Respirations were not unduly accelerated, nor did they deviate from the normal in any other manner. The right arm showed complete immobility, and movements in the forearm and hand were only slightly impaired. No other paralyses were noted. The knee jerks responded normally. No abnormalities were detected in the heart, lungs and abdomen. The temperature was not elevated

Diagnosis of an obstetric paralysis was made, and in order to exclude a cerebral injury, spinal puncture was deemed advisable. The fluid did not escape under increased pressure and was normal for the usual tests

Course and Developments.—March 5, sixteen days after birth: The respirations had often been irregular in rhythm and increased in rate for the past three days. The upper lip was almost constantly bluish. The baby cried only when it was hungry, and the voice was clear and strong. Cough was not present. The appetite and digestion were normal. During the early morning hours of the 5th, the cyanosis became more marked and the circulation enfeebled to such degree that the nurse believed a fatal termination imminent. The response to emergency measures was unexpectedly prompt and permanent. The baby did not appear seriously ill. The upper lip showed a faint cyanotic tinge. During crying, the mucous membrane of the upper lip became blue. Respirations were 72, were unimpeded, and presented a slight irregularity in rhythm. Percussion elicited impaired resonance in the lower posterior two thirds of the right side of the chest, merging into distinct dulness at the base. In this area the breath sounds were enfeebled, and numerous crepitant râles were heard. The heart action was 140 a minute, and no murmur was audible. The abdomen was somewhat sunken; the liver was not palpable and its upper border was at the level of the nipple. The right arm moved freely. The temperature was normal.

A diagnosis of pneumonia was made and a roentgen-ray examination recommended to determine more definitely the extent of the involvement and also to exclude any possible congenital abnormality of the chest. A roentgenogram was taken, March 6, by Dr. Coleman, who found that the right part of the diaphragm occupied a position about 3½ interspaces above that of the left. The right apex showed clouding. The heart was normal in position. The thymic shadow was found moderately enlarged. The following day fluoroscopy of the chest was done, and the paradoxical movements of the two parts of the diaphragm described by Kofferath were clearly visualized. On inspiration, the right part of the diaphragm was pushed upward by the increased abdominal tension exerting pressure in the direction of least resistance; on expiration, with the tension released, the diaphragm resumed its former level. The left part of the diaphragm moved during either respiratory cycle in a direction opposite to that taken by the right, thus giving rise to a seesaw motion. The excursion of the injured side was slightly less than that of the opposite side.

This phenomenon could have arisen only in consequence of paralysis of the phrenic nerve, effected, without any reasonable doubt, by the same means which had injured the brachial plexus on the same side

March 7: The child had experienced no further difficulties in breathing, and the cyanosis had noticeably abated.

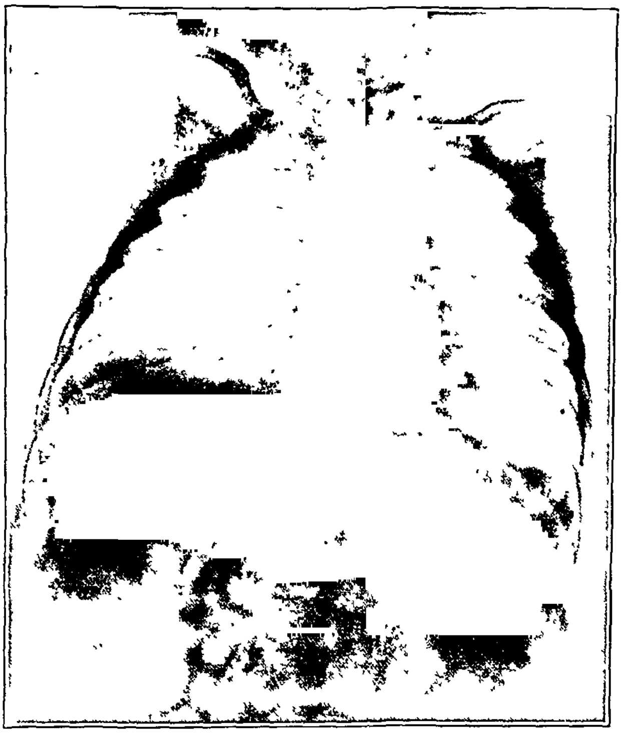

Fig 2.—Right side of diaphragm in normal position, at age of 8½ months

We were unable to induce the mother to return for further fluoroscopic observations. A house visit by one of us, April 13, when the child was 7 weeks old, disclosed the following facts: The baby's development, in the mother's opinion, had proceeded normally. The patient was contented, was good natured, cried only when hungry, and was gaining steadily in strength. The weight, two weeks previously, was 7 pounds (3.2 Kg.), and it had gained 13 ounces (400 Gm.) since. The baby had been fed Dryco for two weeks; the appetite was good, and the digestive disturbances had ceased since the last change in feeding. Breathing had been fast, irregular (about 78 and more hurried after crying) and probably of the Cheyne-Stokes type; but there has taken place a noticeable improvement in this particular in the last three weeks. Stridor had never been present, and cough only very rarely. Hiccup was often noted but was declining in frequency. There had been no cyanosis for several weeks. The baby slept undisturbed for from eighteen to twenty hours a day. No fever was evident at any time. The arms moved perfectly. The infant was strikingly emaciated, with flabby musculature and pronounced inelasticity of the skin. The voice was clear and vigorous, and crying produced slight cyanosis restricted to the upper lip. Respirations were 40, noiseless, but accomplished with a distinct effort. During inspiration an undue degree of expansion of the chest, particularly in the sternal region, was observed with slight epigastric recession. The right side of the chest showed normal resonance, except at the base of the axilla and posteriorly below the level of the sixth rib; the dulness becomes more marked as the base was approached. In the dull area the vesicular murmur was feeble almost to the point of extinction, and crepitant râles were audible. Tactile fremitus during crying was likewise markedly diminished. The left lung showed hyperresonance, with loud breath sounds. The heart action was of good quality, 120 a minute, with no evident displacement. The abdomen was sunken and relaxed and showed normal excursion with respiration. The liver dulness was normal. The temperature was not raised. The arm showed no weakness. The knee jerks were active.

Not until the baby was almost 8½ months old, October 30, were we again able to examine her. The mother stated that the respirations became gradually slower and were considered normal when she was about 3 months old. Cyanosis did not recur. Cough was not in evidence. The baby was at all times contented; both physical and mental development had proceeded satisfactorily, and appetite and digestion were uniformly good. She weighed 16 pounds (7.3 Kg.) and was normal in every respect. She had firm muscles, glowing skin, was able to stand with assistance, and had two teeth. Examination of the chest revealed no departure from the normal. A roentgenogram made by Dr. Coleman showed the right side of the diaphragm a very trifle, perhaps the equivalent of half an interspace, above the normal level. Fluoroscopic examination showed the same range of motion of the two sides of the diaphragm, and they acted synchronously.

SUMMARY AND COMMENT

Shortly after normal birth, with neither difficult nor unduly protracted labor, in which low forceps were used, paralysis of the right arm was discovered in a girl baby. When she was about 13 days old, respirations became hurried and irregular, and occasional cyanosis was noted. Three days later, a severe attack of cyanosis occurred, lasting several hours and necessitating emergency measures. At this date feeble breath sounds and moisture were heard in the right lung, leading to a diagnosis of pneumonia. However, the right side of the diaphragm was high, with a paradoxical movement, as shown by the fluoroscope. Paralysis of the arm disappeared in less than two weeks. Slight cyanosis recurred at times but was unaccompanied by any serious respiratory difficulty. Breathing was fast and irregular for three months. The progress thereafter was satisfactory. When the baby was 7 weeks old, the right lung findings were identical with those previously recorded. At 8½ months, she enjoyed perfect health and showed normal development and normal lungs; the fluoroscope showed no abnormality beyond a very slight elevation of the right half of the diaphragm.

Recognition of the condition was accidental and was effected by means of the roentgen ray. Pressure of the blade of the forceps was probably responsible for the injury.

Kofferath's case differed from ours in that the respiratory disturbances appeared earlier, were mild in character, and disappeared in a few days. Cyanosis and abnormal lung findings were not present. Weigert's patient, contrary to our own, showed leftsided diaphragmatic paralysis, with serious digestive manifestations, and unassociated with brachial palsy.

CONCLUSIONS

Phrenic nerve paralysis is probably not a rare type of birth injury.

Its presence should be excluded in every case of brachial palsy.

The same obligation devolves on the medical attendant when the new-born baby displays cyanosis, irregular labored or accelerated respirations, unilateral diminution of breath sounds with or without moisture, or serious digestive difficulties.

CHOLECYSTOGRAPHY

H. M. RICHTER, M.D.
CHICAGO

The value of cholecystography as developed by Graham and Cole and elaborated by others is sufficiently evidenced by the rapidity with which its use has become all but universal. The clearness with which calculi are so often visualized, the persistent absence of a positive shadow under certain conditions, the ease with which the emptying time of the bladder can be determined and its malformations portrayed, and the outstanding shadow of the normal bladder have carried the medical profession by storm. Patients with advanced gallbladder disease in whom the clinical history is atypical or difficult to obtain are not rare, and in these cases the new method has diagnostic value. Its use has been of the greatest value to us.

I wish to warn against a source of error in interpreting the normal shadow and to call attention to a peculiar psychologic process by which the use of the method may actually become a positive source of confusion. The source of error lies in the fact that one is likely to visualize gall tract infection in terms of gallstones and advanced pathologic conditions. But gallstones do not spring into existence after the manner of the miltonian conception of Genesis. It has been estimated that the patient with gallstones comes to operation after an average of approximately twenty years of incubation and development of his infection. To accommodate our phraseology to the modern conception of the origin of gallstones, which includes the idea of metabolic as well as infective origin for many cases, we may state the case thus: A properly developed anamnesis, not a history taken perfunctorily by a junior intern, will bring out clinical data of suggestive and diagnostic value extending back over an average period of that length of time in the patient's life.

It is noteworthy that, though we are quite well aware of the long story of the evolution of gallstone disease, it requires a conscious effort to realize, and some do not realize, that it is not gallstone disease at all on which we should focus our attention, but the antecedent condition of which gallstone disease is only a late complication. We have no short and apt designation for this antecedent pathologic and clinical process. Neither cholecystitis, gall tract infection, gallbladder or gall tract disease is accurately applicable to all forms or stages of the condition. It includes infection, altered cholesterol metabolism, and gallbladder stasis, in varying degree and duration. Either or any two of these may be absent.

Infection usually manifests itself more obviously in the gallbladder; but an associated hepatitis is probably always an early, and possibly at times an antecedent, condition. Lymphatic extension obliterates anatomic boundaries, and the pancreas, duodenum and pyloric antrum probably always participate in the early pathologic picture.

These varied and widespread changes are usually of insidious development, and their gross alterations so slight that even to the experienced eye and finger they may be difficult to recognize at the operating table.

Even the sudden onset of the typical picture of gallstone colic may be quite unassociated with a materially altered gallbladder structure, except during the attack itself. When colic suddenly supervenes on a condition of adolescent cholesterin stones, there is usually but one small stone, rarely more than two or three, of pea size, and totally unassociated with gallbladder changes except during and shortly after the mechanical accident. When the onset is sudden, with extreme pain, during pregnancy or the puerperium, the immediate condition is usually one of acute stasis, with thick, tarlike bile unable to pass the cystic duct. During the acute attack, cholecystography is unnecessary; after it has passed, it is useless, for the gallbladder is practically normal.

During the terminal stage of the evolution of gallstones the new roentgenographic evidence is of great interest, undoubtedly accurate when positive, and often of great value. For some years before the terminal stage is reached, it becomes decreasingly accurate, for with less advanced changes in the gallbladder wall and cystic duct lumen, the dye may reach the gallbladder readily, and its condensing function and contractility must be but partially impaired.

But when we visualize gallbladder disease in terms of early pathologic changes, chronologically at the period of early symptoms of extragastric dyspepsia, when the alert physician really wishes to make a diagnosis, and often can do so on the history alone, we find that not only must cholecystography fail, but the beautifully clear cut roentgenogram of the typically normal gallbladder actually directs the attention away from it as the source of trouble. This danger cannot be overemphasized.

Gallbladder infection is clinically recognizable in a large proportion of cases before stones are present, and long before the gross appearance of the gallbladder is greatly changed or its function materially or persistently deranged. This is so true that, given a satisfactory clinical history, we are willing to remove a gallbladder that appears to be normal when the abdomen is opened.

If we may divide the life history of gallbladder infection into periods, we might say that during the terminal quarter or third or even half of the duration of the disease the anatomic and functional changes in the gallbladder are likely to be portrayed with great accuracy by cholecystography; during the first third or half of the period, there can be no logical basis for assuming even the possibility of demonstrable changes; with an overlapping middle period of variable duration.

To permit ourselves to develop a furor for diagnostic methods at this stage of the disease is very much like waiting for gallstone colic and jaundice as diagnostic aids, which may be likened to making a diagnosis of pregnancy when the head is on the perineum (with apologies to Moynihan).

The outstanding value of cholecystography is fully recognized.

Its inherent dangers must be quite as fully appreciated. These are:

First, that it fosters a tendency to think in terms of late pathologic changes.

Second, that the normal shadowgraph is likely to direct attention away from the actual source of trouble.

IRON THERAPY IN THE ANEMIAS OF INFANCY

ITS CURATIVE VALUE *

MURRAY H. BASS, M.D.
AND
BERNARD S. DENZER, M.D.
NEW YORK

The difference between the vital reactions of infants and adults has been emphasized repeatedly. This difference is evident also in the mechanism that governs the supply and the maintenance of the level of hemoglobin in the blood. Most of the iron is laid down in the fetus during the last three months of gestation. Thus the duration of pregnancy, whether complete or prematurely shortened, is a vital circumstance in the new-born infant's supply of iron. This is particularly important because human milk and cow's milk are extremely poor in iron; indeed, "there is less iron in milk than in almost any food. . . . The small amount of iron in milk is the more remarkable since all other inorganic foodstuffs are contained in milk in just the proportion in which they are needed for the growth of the suckling animal. . . . The explanation of this contradiction is that the young animal at birth contains a large store of iron for the growth of its tissues. . . . At least five times more iron is found in the liver of a new-born than in that of full-grown animals."[1] The reserve supply of iron at birth explains the suckling animal's ability to grow rapidly and increase its blood supply in spite of the deficiency of iron in the food. Very briefly, then, this is "the iron depot theory" of Bunge.

Bunge's theory clarified certain clinical observations that have found wide acceptance among pediatricians. Premature infants almost uniformly develop anemia as the result, it is assumed, of the curtailed period allotted to them for the deposition of iron. The anemia of twins is almost as common as that of premature infants and the explanation of its occurrence is similar. A third form of infantile anemia, the so-called alimentary anemia, also may be associated with the iron depot theory, though this is questioned by some writers. This type occurs in infants fed too long on an exclusively milk diet or on a diet predominantly of milk with an inadequate supply of green vegetables or other iron-containing food. According to one theory, this anemia

---

* From the Pediatric Service, Mount Sinai Hospital.

[1] Bunge, C.: Physiological and Pathological Chemistry (translation), 1902, p. 377.

is due to the failure to replenish iron which naturally becomes depleted by the ninth or twelfth month of life. The second theory, championed by Czerny and his pupils, traces the origin of alimentary anemia to the toxic or hemolytic effect of the fat of milk, and the treatment he recommends is purely dietetic.[2]

There are other forms of anemia in which iron therapy is not indicated. Anemia secondary to chronic infections, syphilis and tuberculosis, anemia secondary to prolonged pyogenic infections, and the anemias secondary to avitaminoses, rickets and scurvy, are to be attacked by eliminating or alleviating the cause, not by administering iron.

Continental authors long ago discarded the vague term "secondary anemia" for the anemias of infancy and they have added a more vivid, accurate and descriptive terminology, "anemia ex constitutione," which includes the anemias of premature infants, of debilitated infants and of twins; "anemia ex alimentatione," which refers to nutritional anemia; "anemia ex infectione," which refers to the anemias secondary to infection; and, finally, the anemias associated with special conditions, such as worms and rickets. There is often more than one etiologic factor; an anemic, premature infant is more susceptible than a normal, full term infant to rickets and infections, which, in turn, accentuate the anemia.

This brief classification serves another purpose: to call attention to the futility of grouping all secondary anemias under one heading. Not only are the secondary anemias of infancy different from those of adult life, but they vary among themselves in etiology, pathogenesis, clinical course and therefore also in treatment.

Among recent American authors there is almost universal condemnation of the use of iron in "anemia." It is interesting to trace the origin of this opinion even before questioning the correctness of the view itself.

In general, the belief in the uselessness of iron is based not on iron therapy in man, but on the results in animal experimentation. These results have been applied almost literally to human pathology. As an example, Williamson and Ets performed experiments on animals: inorganic iron was given to rats and dogs that were fed an iron-free and an iron-poor diet; and to a second series of animals made anemic by repeated bleeding. Yet one of their conclusions is this: "In the light of the foregoing experiments, the administration of inorganic iron has no therapeutic value in anemia." [3] It should be unnecessary to point out the inherent difference between the bled adult dog and the naturally anemic premature infant; to be comparable at all, the conditions of an animal experiment must reproduce as closely as possible the clinical picture.[4]

Though many physicians may be prepared to translate verbatim such animal experimentation into terms of human pathology, the pediatrician cannot do likewise; for there are too many carefully controlled clinical observations bearing directly on the anemias of infancy which cannot be put aside lightly. Thus, Lichtenstein's opinion is based on the prolonged observation of ninety-two premature infants, certainly an extremely large number of cases. "Through his investigations and clinical observations he has come to the conclusion that iron therapy is necessary and accomplishes its purpose with or without special diet. . . . The effectiveness of iron therapy confirms the author's opinion of the essential nature of all anemias of premature children as well as of alimentary and of Hayem-Jaksch anemia; the essential causes are a deficient iron depot in the sense of Bunge and a functional inferiority of the hematopoietic apparatus." [5] Space does not permit quotation of the conclusions of Schulthess, in Feer's clinic.[6] His experience parallels our own minutely. Almost identical conclusions may be found in Finkelstein's textbook.[7] The point of view of the French, who use the term "anémie à type chlorotique," is thus summarized by Tixier: "The only interest for the practitioner in the diagnosis of this form of anemia is to understand that in the large majority of cases he should substitute progressively a nutriment rich in iron for the milk regimen, that he can give the parents the assurance that the anemia will disappear with astonishing rapidity under the influence of iron medication, and that finally it is not indispensable to continue iron for a long time." [8]

In America, not all pediatricians have been dominated by the results of experiments on animals. To Schwarz and Rosenthal belongs the credit of having recognized this tendency in the therapy of anemia. In 1920 they said, "As is frequent in medicine, certain laboratory and dietetic principles, decidedly popular, assume complete preeminence at the expense of older and valuable methods of treatment." They conclude that the administration of iron in this condition, "the chlorotic type of anemia," meets with an excellent response.[9]

REPORT OF CASES

CASES 1 and 2.—Hazel and Pearl D., identical twins, were admitted to Mount Sinai Hospital, Dec. 25, 1920, at the age of 1 year, complaining of abdominal distention, malnutrition and pallor. The family history was negative for tuberculosis and syphilis. They were born at term and weighed 6 pounds (2.7 Kg.) at birth. They were breast fed for six months. During their second half year they had attacks of diarrhea, their abdomens had grown progressively larger, and they had become very pale. There had been no bleeding of any kind.

Blood Examinations

HAZEL		PEARL	
Hemoglobin	30%	Hemoglobin	31%
Red blood cells	3,250,000	Red blood cells	2,720,000
White blood cells	25,100	White blood cells	24,900
Polymorphonuclear neutrophils	50%	Polymorphonuclear neutrophils	50%
Lymphocytes	30%	Lymphocytes	40%
Monocytes	9%	Monocytes	5%
Myelocytes	8%	Neutrophilic myelocytes	3%
Myeloblasts	3%	Basophilic myelocytes	2%
Ten normoblasts were found for each 100 white cells counted. Basophilic stippling, poikilocytosis and polychromatophilia were present.		Ten megalocytes and 200 normoblasts were found for each 100 white cells counted. Anisocytosis, basophilic stippling and polychromatophilia were present.	

The children were poorly nourished, very pale, and unable to stand. The superficial lymph nodes were slightly enlarged. Signs of rickets were pronounced; the abdomens were markedly distended and tympanitic; the edge of the liver was felt 4 cm. below the free border of the ribs; the edge of the spleen extended to the crest of the ilium. Specimens of urine were normal. The Wassermann and Pirquet tests were negative.

An excellent opportunity presented itself here to test the efficacy of iron therapy by prescribing the drug for one twin while using the other as a control. Hazel was given 10 grains (0.65 Gm.) of saccharated ferrous carbonate three times daily with 1 drachm (4 cc.) of cod liver oil. Except for this medication the diets and care of the two children were identical and they were placed in adjoining beds. The hemoglobin of the child receiving iron began to rise as follows (chart 1).

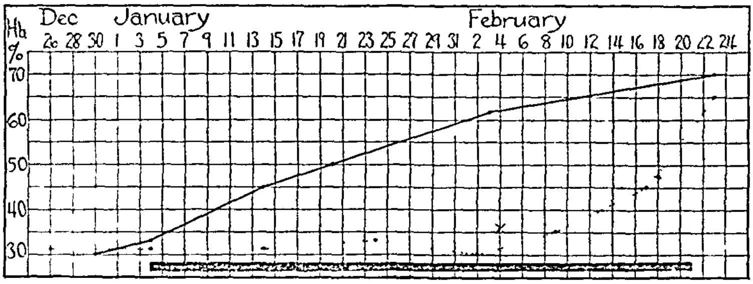

Chart 1 (cases 1 and 2).—Hemoglobin percentage: solid line, Hazel; dotted line, Pearl; X, transfusion; heavy horizontal line, saccharated ferrous carbonate, 0.65 Gm., three times a day.

January 4, hemoglobin, 32 per cent.; iron begun.
January 14, hemoglobin, 45 per cent.
January 20, hemoglobin, 50 per cent.; red blood cells, 4,000,000.
February 3, hemoglobin, 62 per cent.; red blood cells, 4,300,000.
February 23, hemoglobin, 70 per cent.

January 25 there was a striking improvement in the condition of Hazel. There had been a recession of the size of the spleen and liver. The child was gaining in weight. The hemoglobin was up to 50 per cent, with a corresponding increase in the number of red blood cells.

The twin, Pearl, who received no medication, failed to show any change in hemoglobin. January 24, she still had 32 per cent and a red blood cell count of 2,800,000. She developed fever, which gradually assumed a septic type; she became more and more prostrated and showed signs of a very severe pharyngitis. As she seemed about to succumb to this virulent infection, she was given a transfusion of 275 cc. of her father's citrated blood. This checked the illness, the fever subsided, and the hemoglobin began to rise, as follows:

February 2, hemoglobin, 30 per cent.
February 4, transfusion.
February 9, hemoglobin, 35 per cent.
February 17, hemoglobin, 45 per cent.
February 23, hemoglobin, 65 per cent.

It is rare in the clinic to be able to make observations as carefully controlled as in most animal experimentation. Twins, particularly single ovum twins as these probably were, resemble each other minutely in almost all their reactions;[10] indeed, they are much more nearly alike than two animals of the same litter. Furthermore, in the hospital they were subject to the same hygienic conditions and received the same diet. The sole difference was that Hazel received the cod liver oil and iron. Yet the difference in the two children was remarkable: the difference between an increase of 30 points in one case, as opposed to progressive weakness with resulting infection of such severity that transfusion became imperative. Cod liver oil could not have been responsible for this transformation, even assuming that rickets was of major importance in the development of the anemia; for the improvement in the anemia occurred in days whereas the cure of rickets is a matter of weeks and months.

These cases serve to emphasize another phase of the therapy of anemia. Why are there not more dire results when iron is not administered? In other words, what happens to anemic children who do not receive iron? In the group of children with mild anemia there is a strong tendency to spontaneous improvement and sometimes to cure with advancing age. Thus, many of these babies develop into children somewhat pale and generally inferior, and the infantile anemia responsible for their condition may be forgotten entirely. Another group of infants succumb to intercurrent infection, and the anemia plays an important but often unsuspected part in the fatal outcome. One of us[11] has called attention to the relation between pneumonia and anemia and the beneficial effects of transfusion. A third group of infants develop anemia of such severity that transfusion becomes an emergency measure. To this group, Pearl D. belongs. When seen at this late stage of anemia, one is apt to forget that iron therapy earlier in the disease might have prevented a catastrophe, or at least rendered drastic measures unnecessary.

Case 3.—J. M., a boy, was seen by one of us (M. H. B.) when 9 months old. The child was delivered by cesarean section about two weeks before term. The birth weight was 7 pounds 2 ounces (3.2 Kg.). For the past two months the child had looked pale. He was breast fed for only ten days, and thereafter was placed on the usual milk, water and sugar mixture with additional cereal at 6 months. On examination the baby was pale, and weighed 18 pounds 2 ounces (8.2 Kg.). He had six teeth, and there were no signs of rickets. The spleen and liver were not enlarged. Hemoglobin was 42 per cent. Soup was added to the diet and saccharated ferrous carbonate, 10 grains (0.65 Gm.) three times a day, was ordered. Twenty days later the child's weight was 19 pounds 10 ounces (8.9 Kg.) and the hemoglobin was 63 per cent.

Case 4.—E. O., a boy, was admitted to Mount Sinai Hospital at the age of 2 years and 3 months. The child was an eight months' premature baby weighing 4 pounds (1.8 Kg.) at birth. At 1 month of age he had a convulsion. Although the weight had not been followed accurately, the child evidently had been below normal. Dentition and walking had been slow; and mentally he had been retarded slightly. The child was breast fed for six months. From then to the eighteenth month he received milk. At that time an attack of diarrhea, vomiting and fever of two weeks' duration was followed by severe weakness. Since then the diet consisted of a quart (liter) of milk, orange juice and crackers. Eggs, broth and cereal were offered to the child, but he refused to take any-

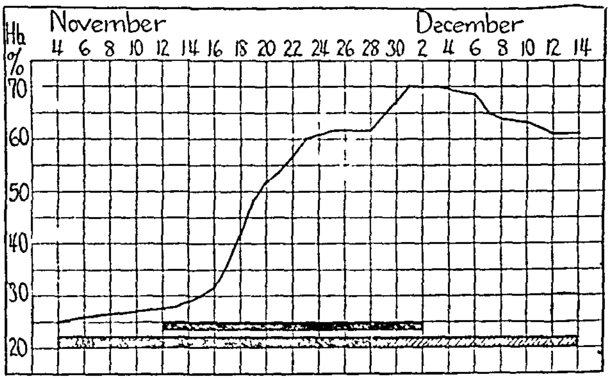

Chart 2 (case 4).—Hemoglobin percentage: heavy horizontal line, saccharated ferrous carbonate, 1.3 Gm., three times a day; stippled line, diet of milk, cereal and toast only; shaded line, full diet, including vegetable and soups; hemoglobin taken at 2:30 p. m. by same person using Sahli Kuttner apparatus corrected.

thing but milk and crackers. He had been growing progressively paler. He had pertussis, mumps and chickenpox before the eighteenth month, but had had no infections since then. The child was well developed but flabby, with evident anemia and moderate rickets. For several days the diet consisted only of milk, cereal and orange juice. Thereafter saccharated ferrous carbonate, 10 grains (0.65 Gm.) three times a day, was prescribed. The resulting increase in hemoglobin is given in chart 2.

Case 5.—R. B., a boy, was admitted to Mount Sinai Hospital at the age of 8 months. The infant was a seven months premature baby weighing 5 pounds 8 ounces (2.5 Kg.) at birth. During the first two weeks of life the child appeared blue. The father had tuberculosis, supposedly in an inactive form. The child was breast fed for six weeks. After that he received various milk, water and sugar formulas. For three weeks the child had been given farina. He had never had vegetable soup, orange juice or cod liver oil. On examination he was pale and weighed 12 pounds (5.4 Kg.). There were no signs of rickets. The spleen could not be felt, and the liver reached the costal margin. The hemoglobin was 40 per cent. The course is given in chart 3. During the period (seventeen days) when a full diet plus cod liver oil and ultraviolet light were given, the hemoglobin remained at 40 per cent. When iron was added and cod liver oil and ultraviolet light were discontinued, the hemoglobin rose to 64 per cent in twenty-five days.

This case illustrates the rapidity of the response to iron as compared with vegetable feeding only. It is not to be denied that an infant with moderately severe anemia, particularly if vegetables, broths, etc., are added at 8 months of age, will improve under dietetic treatment only. But the response to this therapy is slow, a matter of months and not weeks, whereas iron hastens and completes the process.

The relation of anemia, iron therapy and infection may be illustrated by reference to two cases which will not be reported in detail. L. B. and R. R., suffering primarily from nutritional anemia, passed through a series of infections while under observation in the hospital. Iron given in large doses during the infection failed to produce an increase in hemoglobin. After the subsidence of the infection, the hemoglobin rose gradually and very slowly. Iron administered during an infection fails to improve the anemia.

The use of iron in two groups of cases, namely, children recovering from infections and children with a very mild or questionable anemia, has caused iron therapy to fall into disrepute and has led to much loose prescribing and loose thinking concerning the problem of secondary anemia. In the first group the children receive a "little tonic" to build them up following an infection, and the anemia improves along with the general improvement in health and the freedom from infection, regardless of iron therapy. In the second group, the children with very slight anemia, giving a tonic satisfies the parental wish for "something to be done."

THE DOSAGE OF IRON

In our work we have used only saccharated ferrous carbonate in amounts varying from 30 to 60 grains (2 to 4 Gm.) a day. In other words, we adhere to those who believe in large doses of iron. We do not imply that this is the best or the only method of administering iron, but we do emphasize the fallacy of condemning iron therapy after using only small doses. In other words, the results of different authors with iron therapy may be comparable only if the dosage is similar.

Most clinical studies of secondary anemia have emphasized only the iron content of hemoglobin. There is another aspect of the problem which refers not to the iron content of hemoglobin so much as to its protein portion. Hemoglobin is composed of a protein, globin, and an iron-containing part, hematin. The hematin part of the hemoglobin molecule contains a particular molecular grouping, the pyrrol group, which cannot be synthesized by animals. According to Abderhalden, milk in particular contains little or none at all of these pyrrol structures.[12] "It is not improbable, therefore, that inorganic salts added to an exclusive milk diet are not utilized, simply for the reason that other component parts of the hemoglobin molecule, as important as iron itself, are either lacking altogether in the milk diet, or are present therein in insufficient amount to subserve the needs of the blood-forming organs." [13]

Recently Hart, Steenbock and Evehjem[14] have presented further data "which support the original hypothesis of Abderhalden that hemoglobin can be built from inorganic iron in the diet only when that diet is accompanied by certain organic structures, and further that milk is not only low in iron but that it is also low in the organic complexes that make possible the building up of hemoglobin." Briefly, the results of their experiments may be thus summarized:

1. Anemia produced in rabbits by an exclusive milk diet was not cured by the addition of inorganic iron to the diet.
2. When cabbage and iron were added to the milk diet, the anemia was cured promptly.

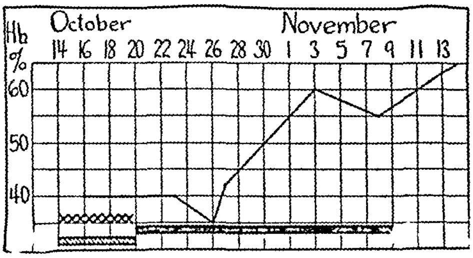

Chart 3 (case 5).—Hemoglobin percentage: mixed diet, i. e., farina, vegetable, milk formula; line of x's, quartz lamp; shaded line, cod liver oil; solid line, saccharated ferrous carbonate, 0.65 Gm., three times a day.

3. As cabbage also contains iron, it became necessary to render the cabbage iron free, and an alcoholic iron-free extract of cabbage was prepared. This, with inorganic iron added to the milk diet, cured the anemia. Chlorophyl, the iron-free coloring matter of plants, and also an iron-free extract of corn meal plus inorganic iron, produced the same result. "Evidently these two different types of plant material contain certain substances soluble in alcohol and free from iron which are intimately concerned with hemoglobin formation."

In the light of these experiments, it is interesting to note that at the time when infantile anemia becomes manifest (about the sixth month) it is customary for pediatricians to add cereal to the diet and before the ninth month to include vegetable extract or purée. When inorganic iron is given to such children, the protein building stones necessary for the synthesis of hemoglobin are probably already a part of the diet, and the ingredients of the hemoglobin molecule therefore are complete. Thus, empirically the requirements worked out in the laboratory have been fulfilled.

13. Robertson, T. B.: Principles of Biochemistry, ed. 2, 1924, p. 49.
14. Hart, E. B.; Steenbock, Harry; and Evehjem, C. A.: J. Biol. Chem. 65: 67 (Aug.) 1925.

SUMMARY AND CONCLUSIONS

1. The use of inorganic iron has been approached from the standpoint of animal experiments not comparable to clinical anemias, at least to those of infancy.
2. The subdivision of secondary anemias of infancy is of service in emphasizing differences in etiology, pathogenesis and treatment.
3. The iron depot theory of Bunge applies to the nutritional and constitutional anemias of infancy.
4. Anemias due to infection do not respond to iron.
5. The affirmation of the value of inorganic iron in the anemias mentioned does not imply the uselessness of dietary or other forms of organic iron. On the contrary, in the prevention of anemia attendant on a too prolonged milk diet, the use of green vegetables, beef extracts and liver still has, and has had, a well established place in pediatric practice for more than a generation.[15]

TOXIN-ANTITOXIN

HYPERSENSITIVITY TO ITS PROTEIN CONTENT *

EDWARD L. BAUER, M.D.
AND
H. B. WILMER, M.D.
Chief of Asthma Clinics, Germantown and Presbyterian Hospitals
PHILADELPHIA

Toxin-antitoxin mixture, as now made in accordance with the technic of Park[1] and his assistants, has proved itself remarkably free of the protein element from the clinical as well as the laboratory standpoint. A five year clinical study has proved satisfactorily the inability of toxin-antitoxin to sensitize individuals to horse protein; this conclusion is based on the following premises:

A group of individuals coming to the asthma clinic of the Germantown Hospital was tested, as a routine, for susceptibility to horse protein. At the same time, a test was made on this group with toxin-antitoxin without dilution, the scratch method as well as the intracutaneous test being employed. No individuals, even those susceptible to the usual test for horse protein, gave any reaction whatever to toxin-antitoxin.

One hundred were so tested, and of these 2 per cent reacted to the horse protein (H. B. W.). None of these showed any reaction to the toxin-antitoxin when given a 0.2 cc. intradermal dose.

The Park test showed a pseudoreaction in 8 per cent of 10,000 children, not necessarily asthmatics or previously known to be susceptible to horse protein (E. L. B.). The pseudo Schick reactions in 40,000 children were found in 10 per cent of the cases (E. L. B.). These pseudoreactions are of no significance from the standpoint of constitutional reaction to toxin-antitoxin.

Fifteen children suffering from asthma due to horse protein sensitivity were given the full course of treatment with toxin-antitoxin, and their reaction differed in no wise from the reaction of those who were absolutely well. No effort was made to desensitize them before the treatment was carried out.

In 100,000 children,[2] twelve contracted diphtheria either during or shortly after the toxin-antitoxin treatment and were given antitoxin, with no evidence of hypersensitivity. The same is true of 100 contacts to diphtheria who had not had time to develop active immunity. However, not all of these had been tested prior to toxin-antitoxin administration. Twelve were given tetanus antitoxin during or subsequent to toxin-antitoxin injections, one as long as one year after, and only one of the twelve had any reaction. This boy had given a reaction to the horse serum test before toxin-antitoxin administration, but had had no asthma. He was quite ill, with a fever of 103, urticaria and joint pains for two days. We have seen the same reaction many times following tetanus and diphtheria antitoxin administration not preceded by toxin-antitoxin or other serum treatment.

Tetanus antitoxin given during or subsequent to toxin-antitoxin:
- After second injection of toxin-antitoxin:
  - Two cases—no reactions.
- After third injection of toxin-antitoxin:
  - Within one month—three cases—no reactions.
    - One protein tested prior to toxin-antitoxin administration.
  - Within six months—five cases.
    - Two protein tested prior to toxin-antitoxin administration.
    - One of those susceptible gave reaction already quoted.
  - Within one year—two cases.
    - One protein tested prior to toxin-antitoxin administration.
    - One susceptible to protein prior to toxin-antitoxin administration.
    - No reactions.

Diphtheria antitoxin given during or subsequent to toxin-antitoxin administration:
- No marked or alarming reactions. Only five of this group tested prior to toxin-antitoxin administration; none found susceptible to horse protein.

One hundred and fifty thousand children, most of them fully immunized with toxin-antitoxin, have been under the observation of one of us (E. L. B.) for a period of from one to five years through the Department of Public Health of Philadelphia, and none have given any marked reaction to toxin-antitoxin administration or have shown any tendency to protein sensitivity by test six months after the injections.

We are therefore convinced that in the use of the toxin-antitoxin mixture properly made and with the protein removed, according to the methods of Park[1] and of Banzhof, no hypersensitivity to horse protein is developed. Further, we are convinced that it is safe and indeed wise to use toxin-antitoxin in asthmatic patients known to be susceptible to diphtheria. Therefore, to assume that hypersensitivity is developed by toxin-antitoxin, one must first prove that hypersensitivity was not present before the administration of the toxin-antitoxin, since those hypersensitive to horse protein do not react to the infinitesimal amounts of protein in the toxin-antitoxin mixture advocated.

IS BACTERIUM ABORTUS PATHOGENIC FOR HUMAN BEINGS? *

I. FOREST HUDDLESON
EAST LANSING, MICH.

The remarkable discovery made by Evans,[1] that the causative organism of undulant fever in man and that of Bang's abortion disease in cattle were similar if not identical, has brought forth considerable confirmatory evidence in this country and in Europe. These findings have served as a stimulus to observe more closely the possibility of man acquiring a fever from handling or ingesting material containing *Bacterium abortus*. Already many cases of illness in man in which the main symptom was characterized by recurrent fever have been cleared by the proper application of the knowledge that Evans has given us.

Cooledge [2] was probably the first to conduct experiments to determine the possibility of *Bacterium abortus* infecting man. At the time, he had no knowledge as to the relation of *Micrococcus melitensis* to *Bacterium abortus*, or what the nature of the disease would be if infection took place. The serologic tests were made use of in this work as a criterion of infection. The results were negative, with the exception of an occasional partial reaction which was possibly due to the absorption of agglutinins present in the milk ingested. The negative results obtained in this experiment were probably due to the small number of organisms in the naturally infected milk and to the lack of virulence of the culture used.

Fleishner, Vecki, Shaw and Meyer [3] have very clearly demonstrated that, in infecting monkeys with *Bacterium abortus*, the number of organisms and their virulence are very important factors to consider.

The case reports of undulant fever made by Keefer,[4] Evans,[5] Bevan,[6] Duncan [7] and others have again raised the question as to the possibility of contracting the disease from cattle infected with *Bacterium abortus*. While the evidence pointing to cow's milk as the source of the infection in these cases is largely circumstantial, it remained for Carpenter [8] to associate closely two cases of undulant fever in man with the ingestion of raw cow's milk containing *Bacterium abortus*.

REPORT OF CASE

During the last year, evidence came to my attention that a former graduate student was possibly affected with undulant fever. He became ill during the winter of 1924, while working in the laboratory with several newly isolated cultures of *Bacterium abortus*. He had never worked with cultures of *M. melitensis*. He suffered from periodic attacks of headache, muscular pains, slight fever, malaise and gastric disturbances during the winter and spring, and became greatly emaciated toward the beginning of the summer. He left the laboratory in June and became associated with the Detroit Medical College. The condition persisted throughout 1924 and until July, 1925. The paroxysms, however, were less severe. He was examined by several competent physicians during this time, but they were unable to arrive at the cause of his condition. In the summer of 1925, he happened to be reading some case reports on undulant fever. The symptoms described compared so closely with his own that he made an agglutination test on his blood, using *Bacterium abortus* as antigen, and found that it reacted in a dilution of 1:400 No blood or urine cultures were made at the time Cultures of the blood and urine were taken in October, 1925, with negative results At this time the agglutination test was positive in a dilution of 1:50 to both *Bacterium abortus* and *M melitensis* His condition was much improved in August, 1925, and continues so at this time.

Oct 24, 1925, another case came to our attention. This young man was also a graduate student in our laboratory, and had been working for more than a year with cultures of organisms isolated from the pregnant bovine uterus. Among these were three or four cultures of *Bacterium abortus*. He was away from the laboratory during three months of the summer of 1925, returning in September. October 24, he became suddenly ill, with muscular pains, pains in the back of the neck and the sacro-iliac region, malaise, headache, fever, chills, high pulse, a slight cough and hoarseness. During the next four days, the temperature was normal in the morning and gradually rose during the afternoon. On the 29th, he felt normal; on the 31st, a second paroxysm occurred, the temperature at this time rising to 104 F. His condition was again normal, November 5, except for marked prostration. The degree of prostration is gradually increasing, and the process of alternating recrudescence and defervescence is continuing. From the beginning he has had a painful spleen, gastric disturbances, weak eyesight, and alternating constipation and diarrhea

A physical examination by Dr O. H. Bruegel of East Lansing, Jan. 5, 1926, seven days after a paroxysm, showed moist and clear skin except for a few small, reddish spots scattered over the chest and abdomen, some of which were slightly scaly, unlike rose spots. The tongue was heavily coated and whitish The tonsils had been removed The glands of the neck were not palpable The thyroid was normal. There was good expansion in both lungs, which were normal, except for an occasional râle. The apex beat of the heart could be neither seen nor felt. The heart was possibly slightly enlarged to the right; the sounds were not clear and seemed slightly muffled. There was a second pulmonic impulse but it was not doubled The pulse was 80, with low tension The systolic blood pressure was 104; diastolic, 70 The abdomen was not distended; there was some tenderness below the costal margin on both sides and in the regions of the gallbladder and spleen The liver could not be felt. The spleen was easily palpable, extending one fingerbreadth below the costal margin on inspiration. The right lower quadrant was normal.

The first blood and urine culture made, Nov. 11, 1925, was negative The blood serum at this time agglutinated both *Bacterium abortus* and *M melitensis* in a dilution of 1:1,000 A blood culture, November 23, showed an organism indistinguishable from *Bacterium abortus*. The urine culture was negative A blood culture, December 8, was also positive. The agglutination titer of the blood serum at this time had risen to 1:2,000. The same titer persists at the present writing.

The source from which the infection was acquired in this case has been a matter of no little speculation. It is obvious that three sources may be considered; namely, the handling of laboratory cultures, and the ingestion of raw cow's milk or goat's milk in which the infective organism was present.

Since this man had worked with cultures of *Bacterium abortus* in the laboratory, the probability of accidental infection cannot be altogether excluded.

The question of infection from goat's milk may be excluded, as there is none sold in this community

---

[8] Carpenter, C M: Notes on the Bacteriology of Two Cases of Undulant Fever in Man, Twenty Seventh Annual Meeting, Society of American Bacteriologists, 1925.

In considering the question of cow's milk, it was found that this man had been drinking raw milk obtained from a small dairy. A sample of milk was obtained from a bottle on the milk wagon of the owner and examined culturally for *Bacterium abortus* by a previously described method.[9] A large number of colonies of *Bacterium abortus* were obtained on each of the several plates made. The presence of *Bacterium abortus* in the milk indicates that the infection may have been acquired from this source, as well as from handling cultures of the organism in the laboratory.

When the symptoms of the case above described became known to the men working in our laboratory, another graduate student, who had been working with both *Bacterium abortus* and *M. melitensis* for more than one year, remarked that he had had similar symptoms, only somewhat milder, two weeks previously. At this time, he complained of an occasional pain in the region of his spleen and his pulse was 90. A blood culture and an agglutination test were made, Nov. 23, 1925. An organism was obtained from the culture which resembled *Bacterium abortus* in every detail. The serum agglutinated both *Bacterium abortus* and *M. melitensis* in a dilution of 1: 200. December 8, the titer of the serum had risen to 1: 400. His condition still appears good, except the painful spleen and a feeling of slight prostration. According to previous clinical studies, the case would be classified as the ambulatory type of disease.

This man was well aware of the virulence of the cultures of *M. melitensis* with which he was working, and consequently had used considerable care in avoiding infection.

An inquiry was made as to the source of the milk he had been drinking, and it was found that it came from the same source as that consumed by the patient with the previously described, typical form of the disease.

Until the disease appears in persons who have not been working with the organism, the naming of the origin of the infection in these cases must be held in reserve.

The point in question, however, is clear; that is, *Bacterium abortus* of bovine origin was undoubtedly the etiologic factor concerned in the manifestation of symptoms similar to those of undulant fever in two of these cases, and *M. melitensis* may have been responsible for the manifestation of a mild form of the disease in the third case.

Yet, an agglutinin absorption test performed on the blood serums in the third case as well as the second case placed the causative organism in the group of *Bacterium abortus* mainly of bovine origin.

The technic described by Ficai and Alessandrini[10] for differentiating between *Bacterium abortus* and *M. melitensis* infection has been employed on the serum in these two cases with varying results. From the results obtained in this test, the typical case is due to *Bacterium abortus* and the atypical to *M. melitensis*. It is not certain that this test can be relied on, as the heating of many bovine serums at 56 C. for thirty minutes will destroy agglutination for *Bacterium abortus*.

There is another factor which may serve to indicate which organism is responsible for the disease, and that is the atmospheric requirements for the primary growth of the organism. It is well known that *M. melitensis* will grow aerobically on primary cultivation and that *Bacterium abortus* requires carbon dioxide for its initial growth. The two organisms isolated in these cases would not grow aerobically in cultures made from the blood, but grew readily when placed in an atmosphere containing 10 per cent of carbon dioxide.

In a further consideration of the source of infection the thought has occurred that, if infective raw milk was the source of infection, why are there not more cases of this disease observed in the United States? Two probable answers are offered. First, it is rare to find *Bacterium abortus* present in the milk from the udders of all cows in a herd. When it is found, the number is rarely larger than 500 per cubic centimeter of milk. At the drying up period, it is found in millions per cubic centimeter of milk from the infected udder. Should such milk find its way into the raw milk supply for human consumption, it is likely that *Bacterium abortus* will be found present in large numbers. In other words, there would be a sufficient quantity of organisms present to make the milk a source of infection and dangerous for human consumption. The second factor to be considered is that there may have been and may now be many cases of this disease which have not been diagnosed or are not severe enough to have come to the attention of practicing physicians.

ANILINE SHOE DYE POISONING

REPORT OF THREE CASES

ARTHUR J. PATEK, M.D.

MILWAUKEE

Muehlberger,[1] in 1925, reported a series of ten cases of shoe dye poisoning, bringing the present total of all cases reported in medical literature up to fifty-eight. He entered exhaustively into an analysis of this subject, quoting all the published data. The additional and particular merit of his analysis, however, lies in the fact that, whereas the cases previously reported in the United States were due to nitrobenzene poisoning, of the ten recorded by him six were due to aniline, these being the first to be reported in this country. To the six I now add three that recently came under my observation.

REPORT OF CASES

Case 1.—A girl, aged 14, who left her home at noon in good health, two hours later suddenly developed severe frontal headache and became cyanotic. This was followed by slight nausea and drowsiness. When seen at the hospital in the evening, she was still deeply cyanotic and was suffering from headache and slight nausea. She was mentally alert, there was no shortness of breath or heart palpitation, there was no fever, and the pulse was normal in rate and rhythm. The heart tones were pure at all valve areas, no edema of the extremities could be seen. Respiration was normal in character, and the lung and blood examinations proved negative. The urine contained a trace of albumin. On the following morning the patient had entirely recovered. It was ascertained that she had put on freshly dyed black shoes at noon, two hours before the symptoms developed. Twenty-four hours later, the shoes still had an unpleasant aniline odor.

The dye in this case was made locally, the label states that it is odorless (which it is not), and cautions against the use of the dyed shoes in less than twenty-four hours after treatment. This warning is at the bottom of the label and is too small to strike the eye of the user.

---

[1] Muehlberger, C. W.: Shoe Dye Poisoning, J. A. M. A. **84:** 1987 (June 27) 1925.

Cases 2 and 3.—September 13, several weeks after the first patient was seen, two brothers, aged 11 and 13, were brought to the hospital. Their symptoms and the clinical course of their disease were so nearly identical that a single report will suffice. Canvas slippers were dyed while on the feet, the dye being a substance that had been in the cellar about ten years. Soon after, the boys complained of a "pins and needles" sensation and numbness of the feet; two hours later they felt dizzy and weak, had a ringing in the ears, and fell in a stupor. They remained in a confused state about one hour. At this period they were admitted to the hospital: vomiting had set in; they were confused, unresponsive and dull; the skin and buccal membranes were deeply cyanosed; respirations were rapid; the lungs were clear; the pupils were widely dilated and the heart rate 120 and 125, respectively; the action was rhythmic, the tones clear and the pulse of good volume. The temperature rose to 99.4 and 99.8, respectively. The feet were discolored with dye. After several hours, the symptoms began to subside, and on the following morning all the evidences of poisoning had disappeared. The urinalysis was negative in both patients; blood examination made on the day following admission showed: a red count of 4,470,000 and 4,590,000; hemoglobin, 83 and 81 per cent, and a leukocyte count of 11,200 and 17,870, respectively, with a normal differential.

The dye used in these cases was in a container without a label. It had an aniline odor, and was analyzed for me by a local chemist, Dr. J. Gubelmann, who reported that it contained 36.58 per cent of an amino-compound, which had definitely been identified as aniline.

As outlined in Muehlberger's analysis, shoe dye poisoning may result from brown or black dye, and may be due either to nitrobenzene or to aniline being used as a solvent. European accounts indicate that aniline is as freely used as a solvent as is nitrobenzene, and the reported cases of poisoning are about equally divided between the two toxic products.

It may be interesting to note that in connection with certain commercialized products other than those mentioned, poisoning has not been unknown. Thus, I am informed that cases of aniline poisoning (with cyanosis as the principal symptom) are not infrequently encountered in a large local chemical plant where aniline dyes are manufactured.

Another product, benzene,[2] has produced markedly toxic symptoms, but of a different character. Thus, Selling[3] reports a number of cases of benzene poisoning in persons employed in the manufacture of tin cans. The solder used was made of rubber dissolved in commercial benzene. A number of similar cases was reported by Santesson[4] of Stockholm, in 1897, as occurring in bicycle tire workers, benzene having been used as a solvent for the rubber.

The symptoms in the benzene cases reported by Selling and Santesson were different in type from those due to aniline and nitrobenzene; whereas the latter were acute, rarely fatal (two out of fifty-seven patients died) and were characterized by cyanosis, the former were in many instances fatal, but essentially chronic, becoming acute only in the end, and were characterized by purpura, anemia and leukopenia. Experiments definitely proved that nitrobenzene was not the toxic agent in these cases, but that benzene was the actual poisonous distillate.

Since seeing the three patients reported above, I have interviewed a number of shoe repairers. All showed me the dye they use, most of them employing the brand used in case 1. A few knew the danger and were emphatic in stating that they have lost customers because of their refusal to deliver shoes in less than two or three days after dyeing; others knew nothing of the hazard, and were not sufficiently impressed with the unstarred warning on the original container to employ or to give the necessary caution. Thus, it is evident that it is not generally known that the danger of absorption is greatly lessened the longer the interval between dyeing and wearing; that this interval should be several days, although one may suffice, and that particularly when shoes are dyed while being worn is there great danger of speedy absorption.

The local shoe dye manufacturer, I have reason to believe, has commercialized his product on a very large scale, thus greatly multiplying the potentiality for disaster from this source.

The total number, now sixty-one, of reported poisonings does not, of course, represent all the actual cases. Several reports of aniline cases have come to me since I called attention to these three. In many, doubtless, the symptoms are of lesser import—perhaps only nausea, headache and dizziness, and subside as the toxic agent is dissipated from the shoes by evaporation; but as long as these dyes are being manufactured, the hazard will continue. The remedy may be found in either prohibiting their use entirely, or, if this is not done, in the employment of a label carrying a danger sign that cannot be overlooked. If the manufacturer and dyer are held to strict accountability, shoe dye poisonings will—as they should—cease.

141 Wisconsin Street.

---

[2] The term "benzol" is an unscientific synonym for benzene; this is a coal tar product and must be distinguished from benzine, a petroleum derivative.

EFFECT OF MENTAL AND EMOTIONAL STATES ON THE LEUKOCYTE COUNT

I. PRELIMINARY REPORT *

JACOB M. MORA, M.D.; LEO E. AMTMAN
AND
SAMUEL J. HOFFMAN
CHICAGO

It is known that mental and emotional states may produce changes in pulse rate, blood pressure, respiratory rate and pupillary reactions, but no attempt has ever been made to study and record leukocytic changes, as far as we have been able to determine from a careful survey of the literature. It has been noted by some that increased leukocyte counts may be found following epileptic attacks and hysterical seizures, but we are not aware that accurate studies have been made in these conditions.

It has been our purpose in these experiments to determine the effects of mental and emotional states on the number and types of leukocytes in the peripheral blood of animals and man. With this end in view, we used dogs in our first series of experiments. Our methods of inducing alterations in the emotional states of the animals consisted of such procedures as placing a cat or a rat in a cage within plain view of the dog under experiment and securely fastened, and then applying various external stimuli.

Realizing the impossibility of determining accurately the exact mental state of the animals, we used such objective methods as obtaining the pulse rate and respiratory rate and the bodily response of the animal. The pulse rate and leukocyte counts were taken several times at intervals of a few minutes while the dog was apparently calm, and control counts were made, before the apparent induced change in the animal and again every few minutes thereafter.

---

* From the Department of Pathology and Bacteriology, University of Illinois College of Medicine.

In ten dogs, an increase of from 30 to 150 per cent in the number of leukocytes was observed under the conditions detailed above.

Our second series consisted of experiments on thirteen patients at the Cook County Hospital presenting noninfected surgical cases, including uncomplicated hernias, varicoceles, hydroceles and hemorrhoids. These experiments were based on our belief that the anticipation of an operation in the immediate future would be sufficient to induce some alteration in the mental and emotional states of most patients. Control counts were taken at frequent intervals during the second or third days preceding the operation. The final count was taken immediately before the operation, with the patient on the operating table. In these cases we were able to ascertain the subjective states of the patients. In seven of the thirteen cases, there was definite evidence of fear and apprehension, while the remaining six patients appeared to be indifferent. The former showed an increase of from 12 to 100 per cent in the number of leukocytes, while in the latter there was little or no change.

The differential counts both in dogs and in man revealed a relative increase in the polymorphonuclear forms.

The exact mechanism of this peripheral leukocytosis is not quite clear, but the work of E. F. Müller[1] and his associates would tend to show that there is in some way a complex reaction of the involuntary nervous system.

The results obtained in our experiments might also be explained on the basis of the preponderance of leukocytes which adhere to the walls of the blood vessels in the splanchnic region under normal conditions. Walter B. Cannon[2] has shown that, during mental and emotional states, there is a constriction of the blood vessels, especially in the splanchnic region; which would have a tendency to liberate the leukocytes from the endothelium of the blood vessels into the peripheral general circulation. This might account for a greater number of leukocytes in the peripheral vessels in which our counts were made. We have not yet attempted to demonstrate the mechanism of this interesting reaction. Its practical import lies in the fact that this phenomenon may have to be considered as a not infrequent cause of leukocytosis, especially in operative cases, and may be confused with infective or other types of leukocytic change.

Use of Dyes in Therapeutics.—A conservative attitude of mind toward all matters dealing with life and death must lead us to insist on a study of a far larger number of tests than we now have at hand in the cases of all of these dyes used as germicides and antiseptics.—Stieglitz, Julius: Chemistry and Recent Progress in Medicine.

Clinical Notes, Suggestions, and New Instruments

SPUTUM EXAMINATION IN SO-CALLED CLOSED TUBERCULOSIS *

EMERY SZUCS, M.D., REISTERSTOWN, MD.

Among others, we classify tuberculous patients as open and closed cases, based on the presence or absence of expectoration. Our recent observations made on two patients of the Mount Pleasant Sanatorium make it appear doubtful whether this classification based on apparent absence of expectoration is justified. In having done so, we failed to recognize that apparently closed cases may be in fact open cases and a source of infection.

We succeeded in demonstrating the presence of tubercle bacilli in the spray of two of our recently admitted patients in the absence of any expectoration. There was an extensive tuberculous involvement present in both of our cases, of acute and subacute character, respectively. The patients were advised to report immediately the slightest amount of expectoration and though our observation covered from four to eight weeks, we were unable to obtain a sputum specimen for examination.

We used the following simple technic: A cotton plug wrapped round a throat applicator was introduced as far as the epiglottis, and the patient was ordered to cough. From this almost invisible material, a smear was made, and in both of our cases the presence of tubercle bacilli could be demonstrated with the Ziehl-Neelsen method. In our second case, repeated use of this technic was necessary to establish a positive diagnosis.

Our observation may imply that no tuberculosis patient can be safely considered a closed case unless repeated examinations are made of spray materials as heretofore outlined, because it is assumed that there is no sputum obtained otherwise.

This technic may also be helpful—as it was in our cases—to aid in making a definite diagnosis in such doubtful cases, in which, in the absence of expectoration, our other diagnostic means fail to give definite evidence of pulmonary tuberculosis.

A brief summary is given of the two cases in which we demonstrated tubercle bacilli by the technic described.

REPORT OF CASES

CASE 1.—A girl, aged 17, had had a "chronic cold" for the last two months and a sudden rise of temperature to 104 F. one week prior to admission. The temperature was of the remittent type and continued for three weeks after admission. Her physicians diagnosed the case as grippal pneumonia. Examination revealed dulness over the entire front and in back to the sixth vertebral spine, with suppressed breathing. Subcrepitant and squeaky râles were heard throughout the entire left side. Pectoriloquy was not increased. The roentgen ray showed uniform haziness of the entire left lung. The white blood cells numbered 5,400, and the differential count showed a slight relative leukocytosis. Although the patient suffered at times with paroxysmal coughing spells and is still coughing throughout the day, she was never able to raise any sputum. Two weeks after admission, our cotton plug method was applied with the result that tubercle bacilli could be demonstrated.

CASE 2.—A girl, aged 14, the picture of health, well developed and well nourished, who did not cough or expectorate, and felt perfectly well, for six weeks prior to admission was under observation in a Baltimore hospital, with the diagnosis of unresolved pneumonia. The patient coughed occasionally prior to admission, but never expectorated. She had a slight elevation of temperature the first two days after admission; since then she has been afebrile. Examination revealed consolidation of the left upper lobe with tubular breathing, impaired percussions note and bronchovesicular breathing over other parts of the left lung. There was also some involvement of the right upper lobe. The roentgen ray showed soft, spotty infiltration of the left apex and upper lobe, with haziness of the remainder of the left lung, which left the impression that this haziness was due to unresolved pneumonia. The white blood cells numbered 13,600, with a normal differential count. When no sputum could be obtained otherwise, our cotton plug method was applied, and after the third trial we were able to find tubercle bacilli.

---

* From the Mount Pleasant Sanatorium.

It may be noted that, when applying the plug, it is not necessary to aggravate the cough by irritation but by merely requesting the patient to cough while the plug is held.

POSTPARTUM ECLAMPSIA FOLLOWING THE DELIVERY OF SINGLE OVUM TRIPLETS*

David Cohen, M.D., and Armand E. Cohen, M.D.,
Louisville, Ky.

De Lee says that multiple pregnancy is distinctly abnormal and that it has been stated by an observer who studied more than 50,000,000 births that while twins occur only once in eighty-seven cases, triplets occur only once in 7,103 births. He further says that plural pregnancy always gives rise to disturbances on the part of both mother and child. On the part of the mother, nausea and vomiting, toxemia, varices and edema are more marked, while nephritis and eclampsia are much more common than in single pregnancy. He adds, "About 70 per cent of duplex pregnancies terminate before term, and practically all triplet and quadruplet gestations do so."

The fatality of the disturbances of pregnancy in plural gestations is increased, especially of the toxemia resulting in eclampsia.

Triplets and quadruplets offer a much higher percentage in mortality than twins, as regards the prognosis of the child.

REPORT OF CASE

History.—Mrs. J. A., aged 36, who was six months pregnant, consulted us, July 5, 1920, complaining of edema of the extremities, palpitation and dyspnea. Her maternal great-uncle was the father of male twins. Otherwise, there was no family history of multiple pregnancies. Her general health had always been good. She had had six pregnancies, five of which resulted in normal full term deliveries, and one, the fifth, miscarried at six weeks. Following the first gestation, in 1904, she noted an enlargement of the thyroid gland. Following each subsequent pregnancy, this gland had become larger. The first day of her last menstrual period was Dec. 14, 1919. In June, 1920, the patient noticed that her abdomen was unusually large; that she was very nervous; that she had palpitation and dyspnea on slight exertion, and that there was marked edema of legs, feet and hands. She had consulted no physician prior to this time.

Physical Examination.—There was marked anasarca; the pulse was 110; respiration, 26, and temperature, 98.6 F. The systolic blood pressure was 170; diastolic, 110; the height was 63 inches (160 cm.), and the weight, 112 pounds (51 Kg.). The thyroid gland, especially the left lobe, was markedly enlarged. There was no exophthalmos, no lagophthalmos or other thyropathic signs. The heart was enlarged 2 cm. to the right. A soft systolic murmur could be heard over the mitral area. The abdomen was markedly distended. A fetal head in the left occipito-anterior position could be outlined. The internal and external pelvic measurements were normal. There was a small rosette of external hemorrhoids. Pitting edema over the extremities and pelvic girdle could be demonstrated. The blood examination, except for a white blood cell count of 10,400, was quite normal. The urine showed a specific gravity of 1.034; albumin, 4 plus; indican, 2 plus; many fine and coarse granular casts; a few hyaline casts; many pus cells, and a few red cells.

Treatment and Course.—The patient was kept at absolute rest in bed, was digitalized and given magnesium sulphate, 1 ounce (30 Gm.), every morning. Her diet was soft, salt free and of low protein.

The patient remained at rest for fourteen days. The edema was lessened; the pulse became slower and of better volume; the blood pressure remained fairly constant at 160/100, and the dyspnea was less marked.

While it was considered advisable to keep the patient in bed for a much longer period, economic conditions had to be considered, so an attempt was made to permit her to get up and later to assume some household duties. As was to be expected, all former symptoms of decompensation reappeared, together with the alarming high blood pressure of 200, systolic; 130, diastolic. Again following a short stay in bed, there was some improvement in the patient's general condition. During the eighth month of her pregnancy, she began to complain of extreme nervousness and continuous cardiac palpitation. Her abdomen had become so swollen and heavy that very slight exertion caused marked dyspnea. A loud mitral systolic murmur could be heard.

This precarious condition continued until active labor ensued at about 11 p. m., October 3. At midnight, the cervix was fully dilated. The protruding membranes were ruptured artificially and were followed by a virtual deluge of amniotic fluid. The first baby, a girl weighing 4 pounds 7 ounces (2 Kg.) presented in the left occipito-anterior position, and was delivered at 12:13 a. m. The second baby, a girl weighing 5 pounds 9 ounces (2.5 Kg.), presented both feet and was delivered at 12:40 a. m. The third, also a girl, weighing 6 pounds (2.7 Kg.), presented in the left occipito-anterior position and was delivered at 12:55 a. m. The third stage of labor lasted ten minutes, the placenta being delivered spontaneously and intact. The secundinae showed three amniotic sacs and one large placenta, off of which came three umbilical cords.

After delivery 1 dram (4 Gm.) of ergot was given by mouth. The hemorrhage was slight, and the uterus contracted well.

Nine hours following delivery, the patient complained of severe frontal headaches. About one hour later, she had convulsions lasting fifteen minutes and followed by loss of consciousness. At this time the pulse rate was 96; respiration, 24; the systolic blood pressure, 180; diastolic, 110. The urine was loaded with hyaline and granular casts. The breath was uremic in odor. Following the removal of 100 cc. of blood, 300 cc. of 3 per cent glucose solution was given intravenously. Continuous hypodermoclysis with physiologic sodium chloride solution was begun, together with rectal injections of 10 per cent glucose, 150 cc., and 2 per cent sodium bicarbonate, 150 cc., every four hours.

The following morning the patient had regained consciousness, but complained of being unable to see. She had one convulsion, October 5, which lasted about five minutes, but was not followed by unconsciousness. Following this, she made rapid improvement. After two days she was able to see, but for about seven days there was considerable visionary disturbance, principally the complaint of large black spots before the eyes. The heart murmur persisted, although the edema, dyspnea and palpitation rapidly disappeared. On the fourteenth day postpartum, the patient was allowed out of bed. Convalescence was normal and two weeks after delivery her weight was 98 pounds (44.5 Kg.). Three months following delivery, her weight had increased to 127 pounds (57.6 Kg.). The pulse, blood pressure, temperature and respiration were practically normal and the urinalysis was negative.

The triplets progressed satisfactorily until November 27, when Virginia, the third born, developed a respiratory infection and died.

In November, 1921, the patient again became pregnant and in August, 1922, gave birth to a girl weighing 8 pounds (3.6 Kg.). Both the prenatal and the postnatal history of the latter pregnancy were uneventful.

Since that time we have seen the patient for various minor complaints. Her last visit to our office, Nov. 20, 1925, aside from a greatly enlarged thyroid and a blood pressure of 132/88, showed a woman enjoying unusually good health.

---

* Read before the Louisville Obstetrical Society, Nov. 27, 1925.

COMMENT

In common with most instances of multiple pregnancy, our patient suffered from edema and toxemia, together with the not infrequent complications, nephritis and eclampsia.

This report differs from similar reports, as follows:

1. Our patient was able to continue her pregnancy practically until full term. She recuperated rapidly from her postpartum condition and, eighteen months later, gave birth to a normal child. The prenatal and the postnatal history of the latter pregnancy were uneventful.

2. The pregnancy was apparently a una-ovular one, as evidenced by the single placenta.

3. The triplets were unusually large, but quite normal. Two of the children are now living. One died of pneumonia after having lived nearly two months.

Francis Building.

TYPHOID IN THE LARGE CITIES OF THE UNITED STATES IN 1925

FOURTEENTH ANNUAL REPORT

The Journal presents its fourteenth annual survey [1] of typhoid fever mortality in the seventy-seven cities of the United States that had more than 100,000 population in 1925.[2] As in the thirteenth report, the cities have been grouped according to the recognized geographic divisions of the U. S. Census Bureau. Since 1920, eight cities have been added to the list of cities with more than 100,000 population (El Paso, Lynn, Duluth, Utica, San Diego, Canton, Flint, Tulsa) and these appear for the first time in our tables.

Table 1.—*Death Rates of Cities in New England States from Typhoid per Hundred Thousand Population*

	1925	1924	1921-1925	1916-1920	1911-1915	1906-1910
Lowell	0.0	1.7	2.4	5.2	10.2	13.9
New Bedford	0.8	4.5	1.7	6.0	15 0	16.1
Lynn	1.0	2.7	1.6	3.9	7.2	14.1
Springfield	1.4	1.3	2.0	4.4	17.6	....
Fall River	1.5	0.0	2.3	8.5	13.4	13.5
Cambridge	1.7	4.5	4.3	2.5	4.0	9.8
New Haven	1.7	5.1	4.4	6.8	18.2	30.8
Hartford	1.9	0.0	2.5	6.0	15.0	19.0
Worcester	2.1	0.5	2.3	3.5	5.0	11.8

Boston	3.5	2.1	2.2	2.5	9.0	16.0

* Rate calculated on figures for population in 1922.

The cities of the New England group (table 1) again make a very favorable showing. All but four of the New England cities achieve a place on the Honor Roll (rates less than 2.0 per hundred thousand), and one city (Lowell, Mass.) has the distinction of remaining free from any typhoid death. The full five-year comparison (1921-1925) which this year becomes available renders possible a more satisfactory appraisal of the actual typhoid situation in communities like these New England cities, where the yearly typhoid deaths are now so few. In such a comparison it appears that in every city in this group but one the average annual rate was lower for 1921-1925 than for any preceding five-year period. In 1916-1920, seven of the New England cities had rates above 4.0; in 1921-1925, only two cities were above this figure. The five-year averages show particular improvement in New Bedford and Fall River. New Bedford carries off the palm for the lowest quinquennial average ever reached in this group, with Providence a close second. The single exception to this almost unbroken record of improvement is Cambridge, which maintained a very low rate in 1916-1920 (2.5), but had an exceptionally bad year (10.8) in 1921, thus bringing up its average for the quinquennium in 1921-1925. In 1925, perhaps the most noteworthy change is that in Boston, which for the second successive year shows a typhoid increase, and for the first time in years stands at the foot of the New England cities. New Haven reports the lowest rate in its history, and Lynn, the newcomer in the list, makes a remarkably fine showing.

* Rate calculated on figures for population in 1924 with same annual increment added as in 1922-1923 and 1923-1924.

In the Middle Atlantic States (table 2) we find the only other American city (Scranton) besides Lowell reporting no typhoid deaths for 1925. From the quinquennial comparison it appears that fourteen of the fifteen cities in this group had a lower average in 1921-1925 than in 1916-1920. The single exception (Camden) evidently has a typhoid situation that needs examination. While typhoid rates all over the United States have been falling, the five-year average in Camden has steadily increased from 4.5 in 1911-1915 and 4.9 in 1916-1920, to 5.9 in 1921-1925. Moreover, the rates for 1924 (6.3) and 1925 (7.0) are higher than the 1921-1925 average. There must be some local reason for this constant upward trend. Compared with 1924, seven cities in this group had a lower rate in 1925, eight a higher. The increase in New York and perhaps in some other localities may doubtless be attributed in part to the oyster-borne infection, which swelled the list of typhoid deaths toward the end of 1924 and carried over into the first quarter of 1925. Typhoid deaths in New York, for example, numbered sixty-

---

[1] The preceding articles were published, May 31, 1913, p. 1702; May 9, 1914, p. 1473; April 15, 1915, p. 1322; April 22, 1916, p. 1305; March 17, 1917, p. 845; March 16, 1918, p. 777; April 5, 1919, p. 997; March 6, 1920, p. 672; March 26, 1921, p. 860; March 25, 1922, p. 890; March 10, 1923, p. 691; Feb. 2, 1924, p. 389, and March 14, 1925, p. 813.

[2] The deaths from typhoid in each city are those reported to us by the respective health departments. The rates have been calculated on the basis of midyear 1925 population, estimated by the method of the U. S. Census Bureau, save that in several instances in which no census estimate is available other estimates are used. These are duly noted in the tables.

seven in the first quarter of 1925, as compared with eighteen in the corresponding quarter of 1924. The increased number of cases due to contaminated oysters unquestionably led to an increase in the number of carriers and also to an increase in contact cases.

The four cities in the South Atlantic states (table 3) for which a comparison of five-year averages is possible showed a marked improvement in three instances (Baltimore, Washington, Richmond) and a practically stationary condition in the other (Atlanta). Atlanta, like the other Southern cities, faces a difficult situation; but is it really any worse than that of Birmingham, which in 1916-1920 had a typhoid average twice as high as that of Atlanta, but in 1921-1925 one that was considerably lower?

Table 4.—*Death Rates of Cities in East North Central States from Typhoid per Hundred Thousand Population*

Toledo	6.3	4.4	5.8	10.6	31.4	37.5

* Rate calculated on figures for population in 1924.

The cities in the East North Central states (table 4) have a perfectly clear record, every one of the ten cities for which data are available showing a lower average for 1921-1925 than for 1916-1920. The reduction in Grand Rapids is particularly noteworthy. Chicago holds the lowest typhoid record for the last five-year period. In this group six cities had lower rates in 1925 than in 1924, and six higher. The two newcomers in the list, Canton and Flint, start out with very low rates.

Table 5.—*Death Rates of Cities in East South Central States from Typhoid per Hundred Thousand Population*

	1925	1924	1921-1925	1916-1920	1911-1915	1906-1910
Louisville	5.8	1.9	4.9	9.7	19.7	52.7
Birmingham	9.2	7.5	10.8	31.5	....	....
Nashville	19.8	20.4	17.8	20.7	40.2	61.2
Memphis	28.6	41.2	20.3	27.7	42.5	35.3

The four cities in the East South Central states (table 5) all stand better in 1921-1925 than in 1916-1920, Louisville and Birmingham showing marked improvement. That Memphis still has a milk problem on its hands is shown by a recent study of the milk supply published by the superintendent of health in 1925. Grading of the milk was found impracticable, and was abandoned in 1923 in favor of published milk scores. Pasteurization is not required; in 1924 about half of the supply (49.7 per cent) was pasteurized. The experience of other communities indicates that pasteurization of a larger proportion of the milk supply would be followed by a further reduction in typhoid.

In the cities of the West North Central states (table 6), none of which in recent years have suffered from excessive typhoid, comparison of the quinquennial averages reveals an almost unbroken improvement, only St. Paul showing a slight increase. With one exception, the 1925 rates in this group were higher than those for 1924. Duluth starts out with the very low rate of 0.9.

Table 6.—*Death Rates of Cities in West North Central States from Typhoid per Hundred Thousand Population*

	1925	1924	1921-1925	1916-1920	1911-1915	1906 1910

* Rate calculated on figures for population in 1924 with same annual increment added as in 1922-1923 and 1923-1924.

The cities of the Southwest (table 7) show uniform improvement in the five-year averages so far as data are available. The 1925 rates in Fort Worth, Dallas and New Orleans are considerably higher than those for 1924. El Paso has responded to our request by sending in complete figures for all the years since 1911, the only one besides Lynn of the cities reporting for the first time to render this service. The proportional reduction in typhoid in El Paso is great and the 1925 figures highly encouraging.

Table 7.—*Death Rates of Cities in West South Central States from Typhoid per Hundred Thousand Population*

	1925	1924	1921-1925	1916-1920	1911-1915	1906-1910

Fort Worth	5.2	1.7	6.1	....	....	....
Houston	5.5	5.6	7.6	....	....	....
San Antonio	8.6	5.8	9.3	23.3	29.5	....
Dallas	17.5	8.2	11.2	17.2	....	....
New Orleans	19.8	10.0	11.6	17.5	20.9	35.6
Tulsa	20.9	....	....	....	....	....

All the cities in the Mountain and Pacific states (table 8) had less typhoid in 1925 than in 1924, contrary to what was observed in other geographic divisions. The decrease was especially notable in Los Angeles and in Portland. All the five-year averages with one exception (Tacoma) also show a reduction.

The Honor Roll (cities with from 0.0 to 2.0 deaths per hundred thousand) this year numbers thirty (five reporting for the first time), as against eighteen on the list for 1924. There are still six cities in the third rank (rates above 10), Dallas and Tulsa taking the places that Albany and Salt Lake City had last year.

The total average typhoid death rate for fifty-nine cities (table 10) is the highest reported since 1921. Early in 1925, case reports from various localities indicated that the disease was prevailing excessively. In Connecticut the state department of health stated that for the first four months there was more typhoid than for any similar period in the last three years A notable excess in the number of cases reported throughout the United States for the first six months of 1925 was remarked on in *Public Health Reports,* July 17. In some places relatively high typhoid prevalence occurred later in the year. The Maryland state department of health received reports of 197 cases in August, 1925, as compared with 156 in August, 1924. The Ohio state department of health noted an increase of 35 per cent in the cases reported in August, 1925, over the number reported in August, 1924. It is evident that 1925 was a "typhoid year."

TABLE 10—*Total Average Typhoid Death Rate (1910-1925)*

	Total Population (59 Cities)* Estimated by the U S Census Bureau Methods	Typhoid Deaths	Typhoid Death Rate per 100 000

1925	28,882,031	993	3 43

* Eighteen cities are omitted from this summary because data for the full period are not available

A new table has been compiled for this summary to show the difference in typhoid mortality in the large cities of the several geographic divisions (table 11) The greater prevalence of typhoid in the southern part of the United States as contrasted with the northern stands out conspicuously in this grouping, the East South Central, West South Central and South Atlantic cities averaging much higher than the rest of the country. Since the largest cities, i. e., those with populations greater than 500,000, are mainly in the Northern states, it is plain that the grouping of cities according to size without respect to geographic location might well lead to mistaken conclusions as to the connection of size with typhoid mortality.

TABLE 11—*Typhoid Death Rates in the Various Geographic Divisions in 1925**

Cities of More Than 100,000 Population in	Population	Typhoid Deaths	Rate
New England states	2,308,266	56	2 42
Middle Atlantic states	11,279,063	333	2.95
South Atlantic states	1,354,748	110	8 12

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(*Continued from page 842*)

Oil in Capsules.—Oily or resinous liquids, when given in rather small doses (up to 0 5 cc.), may be conveniently dispensed in hard gelatin capsules. If the dose is only 1 or 2 drops, or if the agent is very irritant, it should be dissolved in a little of some bland oil, such as expressed oil of almond. As examples of medicine best given in this form may be mentioned oleoresin of aspidium, which is used as an anthelmintic against tapeworm in a dosage of from 6 to 8 cc. This dose is best divided into twelve or sixteen capsules, one or two of which are taken every ten minutes, until all are consumed. As another example might be mentioned oil of santal, 0 3 cc., prescribed for subacute urethritis, one or two capsules three times a day after meals.

Soft gelatin capsules, generally ovoid, have the advantage over the hard capsules of being more easily swallowed That is why larger quantities of oily liquids can be administered in this way. The size of 2 5 cc. should not be exceeded as a general rule Larger sizes are made, but to prescribe them is to invite trouble. To swallow such a large capsule easily, it is well to soften it by dipping for a few moments in water just before putting the capsule into the mouth. Then the capsule is swallowed with another draft of water.

Elastic gelatin capsules are generally not made by the pharmacist but bought by him ready-made from the manufacturer. It is generally considered, though not with good reason, that they are too troublesome to prepare extemporaneously. It is therefore necessary to be acquainted with the various kinds of filled capsules put out by manufacturers and kept in stock by pharmacists. Among these are elastic capsules of castor oil, 2.5 cc.; elastic capsules of copaiba, 0.6 cc., and elastic capsules of oil of santal, 0.3 and 0.6 cc. Manufacturers put up a great many others.

---

* This is the thirteenth of a series of articles on "The Technic of Medication" When completed the articles will be assembled in book form

If one is not certain whether the pharmacist has a certain kind of elastic capsules in stock, it is best to leave out the word "elastic" and to permit him to dispense hard extemporaneously filled capsules if he does not have the other variety. However, when a physician has occasion to use a certain oily substance or combination frequently, it is well to see to it that the pharmacist carry it in stock in the form of elastic capsules, as they are not only more easily swallowed but also more elegant. There is a liability of leakage from the hard capsules filled by druggists which, of course, would defeat the purpose of administration in this form.

Cachets.—Starch capsules, also known as cachets, wafers of konseals, are two little disks of dried paste, resembling in shape little soup plates, made to enclose powder placed in the hollow of the two by moistening their edges and pressing them together, so that the edges adhere. They were invented by Limousin of Paris, about 1870. Previous to this time wafers were used to facilitate the swallowing of powders by moistening a circular wafer sheet, placing the powder in the center, and folding over the edges so as to form "a sort of oyster," which can be swallowed easily by floating it in a spoon with a little water. Now, however, we usually have the pharmacist put on the little wrapper.

By means of these starch capsules, we are enabled to give larger quantities of powders at one dose than we can by means of gelatin capsules. Cachets will hold from 0.5 to 1 Gm. of powder.

Starch capsules are probably best prescribed at present by the name cachets, so that, if we were to prescribe charcoal for gastric flatulence, we might order 0.5 and not more than 1 Gm. of it to be sealed into a cachet, one to be used as needed after meals.

Just before use, cachets are dipped in a tablespoonful of water; and, when the entire surface has been thoroughly moistened and softened, which takes only a few moments, the spoon is placed far back on the tongue, and the whole swallowed at one gulp. These directions should be given to patients explicitly, for it has happened that cachets have been opened or chewed by patients unacquainted with this mode of medication, in either case, of course, defeating the object of this method of administration.

Enteric Capsules.—Enteric capsules are desirable when it is necessary to protect the stomach against the medicament, or the medicine against the action of the gastric juice. In spite of a considerable amount of experimentation on the subject, the problem of enteric encapsulation has not yet been solved satisfactorily.[34] The reason for this lies not only in certain chemical and mechanical difficulties presently to be discussed, but also in the fact that the laws of osmosis conspire against successful enteric encapsulation. Enteric capsules are nothing more or less than semipermeable membranes; and, even if their solubility is such as to make them resist solution in the stomach and yet permit them to disintegrate in the intestine, diffusion into or out of the capsule may occur if a soluble substance is contained in them. If the capsule is permeable to the substance, it may diffuse into the surrounding fluid. If the capsule is impermeable to the substance contained in it but the substance is soluble, then water may diffuse through the capsule, causing the contents to swell and perchance burst in the stomach. This has been shown by Sahli[35] to be the objection to keratin coating, and it probably also holds good for other similar films.

Coating with phenyl salicylate, which is obtained by rolling the pill mass in melted phenyl salicylate, has the objection that the thickness of the coating is difficult of control, and that too thin a coat may permit disintegration in the stomach, while excessive thickness of the coat may resist disintegration in the intestine, so that the pills may pass through the alimentary tract unchanged.

A moderately successful attempt at the production of enteric capsules is by making use of the influence of formaldehyde on gelatin, introduced by Sahli under the name "glutoid capsules." By this means a compound is formed that has varying degrees of insolubility in the gastric and intestinal juices chiefly according to the relative proportions of the agents and the age of the product. According to the method described by Scoville,[36] the filled capsules are immersed for thirty seconds in 1 per cent aqueous solution of formaldehyde at ordinary temperature, drained quickly, dried, and stored for two weeks before using. The disadvantage of this process lies in the peculiarity inherent in colloids whereby they change in solubility under the influence of age. It has been shown that, by keeping these capsules for a much longer time, they may become insoluble in the intestine. This method is applicable only to filled capsules: empty capsules cannot well be hardened by this process, as they are liable to undergo distortion so that they cannot be properly closed.

There is a fair prospect that the interest aroused by cholecystography after peroral administration of tetraiodophenolphthalein will definitely solve the problem of enteric encapsulation by bringing to bear on it the aid of the roentgen rays. This dye, the value of which for the visualization of the gallbladder is now well established, has thus far had to be given intravenously to obtain reliable results. When given by mouth, it is liable to cause vomiting, which of course vitiates the result. The effect of the gastric acid on the agent is also objectionable. Stewart[37] has obtained satisfactory results in cholecystography by coating gelatin capsules with keratin just before use. The tetraiodophenolphthalein, being rather unstable when exposed to air, is best obtained in an ampule containing the required dose (3 Gm.). This is opened just before use and packed into ordinary gelatin capsules, which are then dipped into a solution of keratin, 7 parts; diluted alcohol, 50 parts, and ammonia water, 50 parts. The capsules are then placed on a screen to dry and are usually ready for use within five or ten minutes. Coating of gelatin capsules with stearic acid might possibly do away with the necessity of preparation just before use.

A moderately satisfactory substitute for these coatings is enclosing the pill mass in a double gelatin capsule, one within the other. In addition, the previviously discussed castor oil-wax excipient, suggested by N. S. Davis, might be used, thereby minimizing the dissolving of the agent in the stomach and securing chiefly enteric action.

(To be continued)

CRITICAL CONSIDERATIONS OF EDEMA

Edema has long presented one of the perplexing problems of pathology. It may appear when there is embarrassment of the peripheral circulation resulting from heart failure. It is observed in those forms of chronic parenchymatous nephritis to which the name nephrosis has been applied since 1905, when it was introduced by Friedrich Müller. The symptoms are frequently observed in acute glomerular nephritis. The specialist has likewise recognized the appearance of edema under far less definite conditions. Soda edema may follow extreme alkali therapy in diabetic acidosis; nutritional edema attends dietary restrictions and was particularly conspicuous in the central empires during the World War as war dropsy. Localized edema occurs at the site of inflammations; after some forms of intoxications, edema may arise either locally or generally; and in angioneurotic edema the possibility of a perversion of the nervous control of blood volume regulation is brought into consideration. With such a diversity of aspects before us, it is not difficult to appreciate McLean's[1] contention that the fundamental problem is that of the physiologic regulation of the volume of the internal environment, including the blood and the tissue fluids. It appears, as McLean states, that edema is not an entity in itself, due always to the same underlying causes, but rather a symptom just as dyspnea, which may result from various disturbances of the regulatory process. Progress in our understanding of edema is therefore likely to be promoted only as the varied possibilities are approached independently and their genetic aspects separately disentangled. Part of the work of understanding will consist in rationally discarding untenable hypotheses or, at any rate, restricting them to the special aspects of disease, to which alone they may properly apply.

In the older conception of edema the condition was pictured as an excessive accumulation of lymph, modified or unmodified, in the cells, intercellular spaces, or serous cavities of the body. As Wells[2] has remarked, there would be no difficulty in understanding the disorder as the result of simple passive congestion of the lymphatic circulation. No chemical factors are involved. Widal[3] aroused a new interest in the subject through the demonstration of the influence of chlorides on the behavior of fluid in the body, particularly under pathologic conditions. The organism responds to increased ingestion of such salts by increase in volume, and markedly so in persons with a tendency to edema. Reduction of edema through a salt-free regimen is based on this phenomenon. McLean has pointed out, however, that the results of giving potassium chloride are quite different from those provoked by the sodium salt, and it is likely that the prevalent opinions concerning the rôle of chlorides in edema would not have been so firmly established had the quantitative determination of sodium and potassium been as simply carried out as is that of the chlorides. In a renewed study of the excretion of chlorides, de Wesselow[4] of St. Thomas's Hospital, London, has observed that in interstitial nephritis without edema the chloride concentration power of the kidneys runs parallel with the failure of capacity to concentrate urea. In nephritic patients with edema, on the other hand, two groups of results seem to occur. In one of these the plasma content in chloride is low, while the edema fluid is rich in chlorides; and in these patients the edema appears to be of extrarenal origin. In the other group the chloride concentration frequently is good; it is suggested that in such patients defective water excretion is the underlying cause of the edema. De Wesselow regards it doubtful whether true dissociation of the concentrating capacity of the kidneys for urea and chloride occurs. On his somewhat speculative assumptions, chloride retention would cease to be an all-important factor in the production of edema, but chloride distribution in the body would play a large part in determining the distribution of water between blood and tissue fluids. This is in partial contradiction to Widal's belief that the edema of the nephritic patient is the result of a primary chloride retention due to the renal defect, the water retention being a secondary but necessary consequence if the chloride content of the body fluids is to be kept within a range compatible with life.

Nothing has been stated here of other much discussed possible influences that may affect the normal distribution of fluid in the body. Changes that are colloidochemical in nature must not be overlooked. The lowered surface tension in the blood serum emphasized by Clausen in nephrosis with edema is a significant finding. The peculiarities of the disappearance of intradermally injected salt solutions in edematous patients present a unique problem.[5] Study of the questions at issue has been hampered by the difficulty of reproducing edema in any adequate manner in experimental animals. There is at best little satisfaction to be derived from the outlook of the recent reviewer[1] who points to the clinic as offering the best prospect of success. He remarks that the physicochemical method, which has been so fruitful in the past, may be expected gradually to disclose as yet hidden mechanisms. The more general approach from the standpoint of the organism as a whole, with an attempt to solve the nature of the regulatory process, to discover the unknown "influences" and the manner of their control, offers a tempting field for investigators. Meanwhile, he concludes, the more and more detailed observation of patients with edema, the search for and correlation of deviations from the normal, may bring to light new phenomena, each being the starting point for further investigation. By a combination of the three methods, in all of their various ramifications, may one hope for solution of the problem and control of the condition of edema.

ENDEMIC GOITER: THE LESSON FROM NEW ZEALAND

Few months have passed of late without contributing new evidences sustaining the hypothesis that endemic goiter is caused by a deficiency of iodine in the diet. Europe and America, far apart though they are, different in manifold features of geology and geography, often unlike in racial characteristics, and varying in the modes of living, have nevertheless given comparable answers to the question of the incidence of goiter and the preferable means of prophylaxis. The long held belief that the malady is characteristic of mountainous countries has been completely dispelled; one need merely cite the experience of our Great Lakes region in this connection. It does not follow, either, that goiter is to be found to an unusual extent where limestone is abundant. It is generally assumed, however, that proximity to the sea insures against goiter, owing to the wafting inland of ocean spray that includes not only chloride but also some iodide. The most conspicuous goiter regions of Europe and America are in the interior of the continents, whereas the coastal districts enjoy a comparative immunity.

The two chief islands of the dominion of New Zealand comprise a territory within which every inhabited locality is not more than a hundred miles from the sea. One might well expect immunity from goiter in such a country. Yet the elaborate study of Hercus, Benson and Carter[6] of the University of Otago, New Zealand, has disclosed a widespread prevalence of the disorder. Thirty-one per cent of the school children are affected; in some areas, 60 per cent of them show some degree of thyroid enlargement. The native Maoris, comprising about one third of the total population, are by no means immune. For many generations their native language has included the word "tenga," meaning goiter.

An explanation of this unexpected finding has arisen out of the Otago investigations. Topographically, New Zealand is most varied. There is a remarkable range of geographic conditions. The study shows that, roughly, the incidence of goiter is in general inversely proportional to the amount of iodine in the soil, which determines the inclusion of the element in the plant and animal food consumed by the population of a given district. Where exceptions to this occur, it has been noted that the required iodine seems to be supplied by the drinking water rather than in foods. Among coastal Maori tribes where fish and edible seaweed bulked largely in the dietary, goiter was not known, though it occurred among the inland tribes long prior to European occupation.

The record of a supposedly immune island country such as New Zealand is a lesson in the importance of concerted attack on a preventable disease. Out of 135,282 male recruits between the ages of 20 and 45 examined by military medical boards during the period 1916-1918, when conscription was in operation, 1,581 were declared unfit for active service on account of thyroid enlargement. This is not primarily the result of "civilization," for goiter has been found not uncommon in horses, sheep, cattle, dogs and trout bred in New Zealand. It is not racial, for two races with differing habits live there side by side. If it is true that endemic goiter is "the stepping stone to cretinism" and the beginning of other forms of thyroidal pathogenesis, the importance of effective preventive measures requires no argument. The story of New Zealand should serve to strengthen our own prophylactic purposes and programs.

PHYSICAL APTITUDES

There is a growing tendency in this country to consider health one of the foremost objectives of education, taking its place with, or perhaps even surmounting, the consideration of mental development and social progress. It is not easy to define the end sought. To consider health in terms of mere freedom from disease falls far short of the ideals of the educational ambitions of the present day. A more adequate and satisfying definition of health pictures it as "the quality of life that renders the individual fit to live most and to serve best."[1]

Physical competence plays an important part in the sort of health fitness that is here portrayed. Inevitably there is a demand for some mode of measurement that is applicable to educational schemes, so that the degree of attainment can be evaluated. This is true in the routine of school work where mental tests of one sort or another form part of the regimen. It is likewise expected nowadays with respect to the physical fitness of the adolescent. If it is true that the ideal method of testing intellectual achievement is not yet in sight, what shall be said regarding examinations in the field of physical competence?

[1] Williams, J. F.: Personal Hygiene Applied, Philadelphia, W. B. Saunders Company, 1925, p. 20.

Strength and endurance determined in combat or competitive sport are far from satisfactory measures of promising physique. A group of physiologists[2] at Guy's Hospital in London have properly pointed out that physical fitness is relative and does not necessarily mean good physique; the efficient performance of work involves the interaction of all the systems of the body. Their argument that the condition is so complex and the power of adjustment so great that no single measurement can be an infallible guide scarcely needs further emphasis. The British writers remind us that one man may be physically efficient for a definite piece of work under certain conditions, such as temperature and moisture of the air, which would not suit another equally healthy man. There is an individuality in all men, each having an optimum of speed and environment.

The difficulties in the way of attempting to bring about uniformity are seen in the actual tests made on students in London. Of the familiar procedures, vital capacity proved to be an unreliable index despite the claims of Dreyer and his followers. Efficient respiration, so the criticism reads, is not determined alone by the capacity or mobility of the chest and lungs: the process involves the coordination of pulmonary ventilation with the activity of the heart, the circulation and the oxygen capacity of the blood—factors that cannot be determined by the spirometer. Estimations of pulse pressure, of ability to hold the breath and of related performances have obvious limitations. Comparisons of the pulse rate at rest and after exercise seem to give the best single simple indication of physical fitness. The reasons are, perhaps, not far to seek. The circulatory pump, the heart, must be adjusted to the needs of the body. Its efficacy represents an adaptation of both nervous and muscular control to bodily needs; yet there are persons in whom the heart is far better developed than the skeletal muscles.

The conclusions of Hambly, Pembrey and Warner[2] will provoke thoughtful consideration even if they do not invite approval. To them there appears to be no real test for physical fitness for every and any kind of occupation other than the old method of trial and error. A man in perfect health, they remark, may be fit for one form of muscular work rather than another, and his capacity, which is predetermined by his ancestry and development, can be rendered manifest only by the repeated performance of the work in question. If all of us thus need to be placed "on trial," as happens so commonly to the rank and file of human kind, it will assuredly be helpful to discover an "aptitude test" for physical performance. The psychologists are leading the way toward a similar goal in the field of mental equipment.

Current Comment

"ETHICS AND THE MEDICAL PROFESSION"

A few weeks ago The Journal considered editorially the physician of the future, noting that the practice of medicine is changing with the times. The entrance into medical service of corporations dispensing diagnosis and some treatment on a wholesale basis, and competing, perhaps unfairly, with the individual physician by means of uncontrolled newspaper advertising, has raised a problem that may to some extent menace the actual existence of the individual practitioner. In a consideration of medical ethics in the current issue of the *Survey*, Dr. Richard C. Cabot, himself intensely individualistic, although socially minded in his writings, comes to the support of such mechanized medical practice. It should be remembered that the editorial advisor of the *Survey* in matters of health is Dr. Haven Emerson, whose views as to the socialization of medicine are not entirely unknown to the widely read physician. That part of the code of ethics which concerns contract practice forms the major subject of Dr. Cabot's consideration of one trend in the relationships of medicine to the community. He condemns "lodge practice" unreservedly as being bad both for patient and for physician. He feels, however, that the factory physician, the mine doctor, the director of a union health center, the department store physician, and similar practitioners, while certainly doing contract practice and certainly competing with the private practitioner, do so to the great advantage of the public served. And he is unable to see much difference between such industrial practice and that of the corporations selling periodic physical examinations. Furthermore, Dr. Cabot has convinced himself that organized commercial service is better than that of the private physician. Apparently he is but little concerned with the present status of the individual physician, and perhaps even less concerned with the professional status of the physician of the future. It will, of course, be remembered that he was among the first and most vociferous proponents of group practice, again without any thought of the effects that such a system has on the development of the individual practitioner. While he argues for collective practice and a sort of socialized medicine, the code of ethics governing the medical profession gives him but little pause. Of course, it is "of interest," to use his own words, but after all not nearly so much of a force for ethical advance as intimate contact of medical men with other medical men "better than themselves, where, by osmosis, nobler habits of thought and action seep across from teacher to pupil, from chief to intern, from colleague to colleague without a word spoken on the subject." One is inevitably reminded of certain direct communications with the Deity which from time to time inspired prophets have claimed as their sole prerogative. Nevertheless, when some ninety thousand physicians are concerned, it would not perhaps be wholly wise to rely on the inevitable receipt and comprehension of such telepathic influences.

TYPHOID IN 1925

The reason for the substantial and widespread increase in typhoid in the large cities in the United States in 1925, shown in our annual summary (p. 948), is not clear. This is the most considerable proportional increase (10 per cent) since these summaries were undertaken in 1910. The greater prevalence of the disease is not to be attributed clearly to any universally acting cause, since in one geographic division—the Mountain and Pacific states—the 1925 rates are lower than those for 1924 in every city. In the other geographic divisions, thirty-four cities experienced an increase, twenty-seven a decrease. Various factors may conceivably have been at work. There has obviously been a progressive change in the population with respect to antityphoid inoculation. The protective effect afforded by the army inoculations in 1917-1918 may be wearing off, and *pari passu* a new uninoculated generation of young males is reaching the typhoid age. It is difficult to deny some weight to this factor, and while it should be operative in the Mountain and Pacific states as well as elsewhere, other causes making for reduction may have obscured it. It seems to be true that in most of the country 1925, like 1921 and 1913, was a "typhoid year." There does not appear to have been any extensive prevalence of water-borne disease, and barring the oyster infection early in the year no particular multiplication of sources of infection seems to have occurred. It is tempting to relate excessive typhoid prevalence over a wide territory to some general factor such as weather conditions, but it will be necessary to collect more data before this aspect of the problem can be profitably approached. In the meantime, the annual fluctuations brought out in these summaries will suggest to epidemiologists various lines of inquiry.

SMALLPOX IN THE UNITED STATES IN 1925

Smallpox—the word recalls at the same time the horrors of disease and the triumphs of preventive medicine. We are reminded that, before Jenner's utilization of vaccination to guard against smallpox, the malady was causing one tenth of all the deaths of the human race, while nearly twice as many persons were permanently disfigured by its ravages. Indeed, it has been computed that during the eighteenth century 50,000,000 people died of smallpox in Europe.[1] In contrast with this are the striking achievements in prevention resulting through systematic vaccination. Thus, this procedure in the six provinces near Manila, P. I., with a population of more than a million and a former death rate from smallpox exceeding 6,000, has resulted in eliminating all mortality from the disease among the vaccinated.[2] There are today many physicians who have never seen a case of smallpox. Yet, a century after the death of Jenner, to whose memory London erected a monument as a partial expression of its gratitude for his benefactions, the lesson of his life work has not been adequately learned in many quarters. How else shall we account for the persistence of neglect even in the enlightened United States? A recent report of the U. S. Public Health Service[3] contains this significant statement: The total number of cases reported for the states for which comparable figures for eleven months of the three years are now available are as follows: 1923, 21,233 cases; 1924, 43,029 cases; 1925, 31,037 cases. The increase in 1924 over 1923 was 103 per cent, and the decrease in 1925 from 1924 was 28 per cent. The figures for 1925 in these states were 46 per cent higher than those for 1923. This is not the story of a single section; it comprises thirty-eight states, among which the New England group alone can claim reasonable exemption, this year only, from smallpox. The same issue includes in the usual current weekly reports of the prevalence of disease such items as 36 cases in Alabama, 9 in Arkansas, 130 in Florida, 15 in Georgia, 61 in Illinois, 41 in Iowa, 74 in Louisiana, 26 in North Carolina, 51 in Oregon, 17 in South Carolina, 21 in Tennessee, 81 in Texas—incomplete records that point a moral. It is not the negligence of the medical profession, for the physician appreciates in every detail the necessary measures for prevention. The public is at fault: it has become imbued with a feeling of safety against smallpox and has become indifferent to the necessity of never-failing preventive measures. The lessons of vaccination are clear and convincing. How long shall the prevailing lethargy in many quarters continue to endanger the health and comfort of millions?

THE DEFEAT OF THE STREPTOCOCCUS IN MEASLES, ERYSIPELAS AND PUERPERAL SEPSIS

When the announcement was made that Drs. George F. and Gladys Henry Dick had shown that scarlet fever is a disease similar to diphtheria in that the streptococcus elaborates a toxin which is the causative agent, medical philosophers predicted that other investigators would soon reveal similar causative agents for related diseases. It appears likely that these predictions are to be successfully realized within the current year. In this issue of THE JOURNAL appears the report of the investigations in measles by Drs. Ferry and Fisher of Detroit, who have elaborated a skin test for measles with toxin prepared from an organism found in the blood of patients suffering with this disease. This organism appears to be the same as that first described by Tunnicliff. Ferry and Fisher emphasize the fact that their organism is aerobic, whereas, the Tunnicliff organism is also aerobic in cultures of the second generation. Experiments are also being made by other investigators with streptococci associated with erysipelas and puerperal sepsis, and preliminary reports of their work indicate the possibility of similar success. Moreover, other organisms than the streptococcus are now being studied with relation to toxin production, notably the staphylococcus and more recently the tubercle bacillus. If these investigations are confirmed, with the widespread acceptance accorded to the Dick discoveries, it may well be that the present decade will pass into history as the one that saw the streptococcus defeated by medical science.

THE MODEL MANUAL OF THE VETERANS' BUREAU MEDICAL SERVICE

The standardization of laboratory procedure is difficult because of individual preferences in technic. The United States Veterans' Bureau has just issued a clinical bulletin [1] which is notable among laboratory manuals in its method of determining standard procedures. The work arose out of the need for a uniform, simple, sensitive Wassermann technic that would eliminate a maximum number of false positive reactions and that could be performed with reasonable accuracy by the average laboratory technician. After prolonged correspondence, a procedure was adopted which, it is claimed, is sensitive, gives few false positives, requires but one antigen and is rapid of execution. The bulletin gives in concise, clear form everything that one who is setting up a Wassermann laboratory needs to know. It contains a list of the apparatus required, tells how to clean this apparatus and how to care for it, and gives directions as to how to obtain specimens and how to prepare reagents. Of especial value are the tabular instructions of how to titrate antigen, perhaps the most puzzling and tedious of the procedures required of a Wassermann technician. An experienced laboratorian will recognize that even omissions are carefully intentional. For instance, the mysteries of the water bath thermostat are not explained. Thus the temptation to meddle with it is partially removed. The standard technic published in bulletin 10 might well be adopted by any laboratory.

COOPERATION BETWEEN MEDICAL ORGANIZATIONS AND THE PUBLIC

Annually, for several years, one issue of the *Wisconsin Medical Journal* has been a lay number,[2] and has been distributed to eight thousand people. Furthermore, many state medical societies have worked out plans for extending the benefits of modern medicine to the public. In Michigan, the Joint Committee on Public Health Education has arranged lectures before parent-teacher associations and high school groups, and has found the public eager to listen and anxious to cooperate.[3] The Kings County Medical Society of Brooklyn has gone even further by voting to admit laymen as associate members of the society.[4] To be sure, the state society must act on this vote before it becomes effective. At all events, the tendency displayed in Wisconsin, in Michigan and in Kings County is a healthful one in every sense of the word. Traditionally, the mystery that has surrounded the dissecting room and the laboratory has excluded the public. For centuries the public did not care. Now it does care. If it cannot understand the whole subject of medicine, it wishes to have explained, clearly, such portions as it can understand. It is one office of medicine to direct public opinion in matters of health along beneficent channels to sound conclusions. Apparently, scientific medicine, in a dignified way, is accepting its opportunity.

(Continued from page 876)

FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 17—MORNING

Ten Years of Progress

DR. JOHN S. RODMAN, Philadelphia: To the National Board of Medical Examiners this is an important anniversary, as it marks the completion of the first decade of its life. The national board has granted certificates by examination to 740, has registered 2,642, has examined in part I of its now divided examinations 1,723, in part II, 912, has increased its recognition by state medical examining boards from seven to thirty-four in addition to the Canal Zone, Hawaii and Porto Rico, has established reciprocal relations with the Triple Qualification Board of Scotland and the Conjoint Examining Board of England, and has established subsidiary boards in fifteen of the larger medical centers of this country. Candidates for the board's certificate have come from all the seventy class A medical schools in this country, and from the following foreign schools: Beirut, Brussels, Cambridge, Dalhousie, Edinburgh, Hungary, Kazan, Kiel, London, McGill, Manitoba, Melbourne, Moscow, Naples, Odessa, Oxford, Petrograd, Prague, Toronto and Vienna. The ten medical schools that have provided the largest numbers are: Harvard, 385; Pennsylvania, 253; Johns Hopkins, 209; Rush, 176; Woman's, 121; Cornell, 109; Columbus, 91; University of Virginia, 69; Yale, 67; Oregon, 50.

During this decade, certain changes have been made in the teaching of medicine. We believe that much more stress should be placed on the actual knowledge needed to make a good practitioner and much less on the refinements and specialties than has been done in former years. The national board's examinations have been developed so that when a candidate has satisfactorily completed the series, the board will have no hesitation in certifying to the fact that he or she may safely be granted the privilege of practice. Comparisons show a lower trend for the grades given by the national board than those given in the medical schools. Of the changes now taking place in medical education, none has been more important, we believe, than the effort to correlate the fundamental with the clinical branches. The study of anatomy is made, in a few schools, a living thing because it is taught with a direct functional bearing. In physiology and in physiologic chemistry, too great a distance separates these subjects from the clinics. In pathology and bacteriology, it seems that the training of the board's candidates has been more uniform and has been more "clinicalized" than in the former subjects. The proper time to teach the subject of materia medica and pharmacology is not until students have finished the subjects of anatomy, physiology and chemistry, which is done in the first two years, thus placing pharmacology properly in the third. The percentage of failures in part I has been about 22. The percentage of failures in part II has been a little over 11, or half of that in part I. In medicine, surgery, obstetrics and gynecology, the candidates have shown more proficiency in memorizing facts concerning disease in general than in the demonstration of the application of this knowledge on the patient. The board hopes that its candidates will show in the future more understanding of such fundamental things as wound healing, inflammation, fracture and dislocations, and less about brain tumors and thyroid surgery. The board feels that too much time is given to the surgical specialties in the undergraduate years. Taken as a whole, these few years have convinced the national board that medical education in this country is fundamentally sound.

DISCUSSION

DR. H. S. ARNOLD, Boston: Starting with considerable doubt on the part of this organization as to the wisdom and action of a national board, you have loyally helped us. Almost all the members of this organization have recognized the certificate of the national board. There was, I think, some feeling at first that the board might replace the work of the state boards. That is practically out of the question. We have never had any intention of such work. As our aim was to get an examination that ought to be acceptable to all the state boards, we have to take a standard which would be acceptable to the highest state board in the country. Without any criticism of state boards that do not come up to the highest standard, we realize that the conditions in various parts of the country and different states require somewhat different treatment. We do not believe that there should be a federal supervision of requirements for license.

DR. WILLIAM JEPSON, Sioux City, Iowa: If you were to take a hundred papers and examine them, you would generally find about four or five which are the product of superintellectual men, and if you would grade the rest of the papers in accord with those, the rest would all be thrown out. Those men should have an opportunity to subject themselves to a further examination so that they are really qualified, and then they should have the advantage of not being restricted in their practice to one particular state.

DR. T. J. CROWE, Dallas, Texas: I think I was the first objector to the National Board of Medical Examiners. Since that time my eyes have been widely opened. I have been trying as hard as any one could to get acceptance and wrote our bill so that at any time when the personnel of the Texas board changes it will be possible for Texas to accept the diplomates of the national board.

DR. JOHN M. DODSON, Chicago: The history of this movement is to me one of great interest. I was interested in it as long ago as 1906, when I wrote a letter to THE JOURNAL advocating what is substantially today the working plan of the board. One of the most pernicious and ridiculous provisions in our state laws is the exclusion from the business of examining candidates for licensure of the only men in the state who were fit to do it. The business of examining and testing men requires skill and care and training and experience, and men who have had that experience in the medical profession are men who are engaged in the business of medical teaching and examining. It is very gratifying to learn that thirty-four states now accept the certificate of the board. In our peculiar form of government, it is the one and only solution that will make a medical man free from the penalty which so many have experienced of being required on the basis of health or family to move to another state years after beginning practice and find themselves faced by a sort of examination which no man ought to be asked to take at that period after his preliminary study.

DR. JOHN S. RODMAN, Philadelphia: We have gone on the principle from the very first that those best fitted to teach are best fitted to examine.

DR. G. M. WILLIAMSON, Grand Forks, N. D.: The Conjoint Examining Board of England and the Triple Qualification Board of Scotland recognize the board.

DR. JOHN S. RODMAN, Philadelphia: I should have explained the reciprocal relation existing between the Conjoint Examining Board of England and the Triple Qualification Board of Scotland and the National Board. The arrangement is that those two boards of Great Britain accept the candidates of the national board after they have passed and received the diploma of the board into their final or clinical examination, and we do likewise.

Admission of Foreign Medical Graduates to Licensure Examination as Handled by the Michigan Medical Board

DR. GUY L. CONNOR, Detroit: Subsequent to the World War, it became apparent to the Michigan medical board that something would have to be done to curb the influx of undesirable foreign medical applicants. Many of these were not the highly educated physicians who formerly came to us but were as undesirable in their own country as they were here. Certain foreign medical schools have been giving war service as credit for medical school work. In our experience, the German and Austrian schools have been the worst offenders in this respect. We also have received all sorts of fake credentials from some of the foreign institutions. Under the Michigan rule, there are two distinct classes of foreign medical applicants: group 1: those who have graduated from medical schools located in the British Empire, France, Italy, Mexico, Netherlands, Norway, Portugal, Spain, Sweden and Switzerland; group 2: those who have graduated from medical schools located in other foreign countries than those mentioned above. Those in group 1 who have fulfilled the Michigan requirements are allowed to take the board examination. Those in group 2 who have fulfilled the Michigan requirements save for their medical college of graduation have first to complete the additional educational course of one year in a satisfactory manner, and then they have to take the board's examination, the same as group 1.

DISCUSSION

DR. B. U. RICHARDS, Providence, R. I.: We shall have to handle this matter in one of three ways. One is for the men of the examining boards to accept, without question, the diplomas of foreign schools. Another method is for us to secure all evidence possible regarding the institution in question. The third method is the best one, it seems to me: that recommended by Dr. Connor of Michigan, that a year in an American college be required. Yesterday the statement was made by Dr. Judd that graduates from medical colleges abroad receive their diplomas about two years earlier than our American candidates. That being the case, that is one reason why such men ought to be willing to give a year's study in this country.

DR. ALEXANDER MACALISTER, Trenton, N. J.: Foreign applicants in New Jersey are required to file, in addition to our regular application, all their original credentials; i. e., certificates covering preliminary education, course book, certificates and diplomas covering medical education and certificates covering hospital work, together with translations made by the consul general of the country in which the schools, universities and hospitals are located. The number of students from the rural districts is decreasing, and of the students from the cities an increasing proportion are of foreign birth or parentage, with caste traditions from the Old World. The American physician is disappearing along with the family practitioner.

DR. LOUIS B. WILSON, Rochester, Minn.: We have all the time, in the Mayo Foundation, foreign graduate medical students. Some years ago we became of the belief that graduate medical students who are to come in contact with patients certainly should come under the police regulations of the state. We propose for the consideration of the state medical examining boards that some means be included in your rules and regulations whereby the bona fide medical graduate student from a foreign country (make it an *English-speaking country, if you please) might be given some* form of temporary license which should be granted only after the same examination as that required of candidates for license to practice in general, and that that license then be terminated at the end of the man's residence as a graduate student in an accepted university.

Dr. I. D. Metzger, Pittsburgh: In our law this basic principle holds: A man's license is just as valuable as the credentials he files in the department of public instruction. If those credentials are not reliable, his license is not reliable. We have found two candidates who did not know the first thing about medicine, yet they carried with them diplomas, certificates from hospitals, and all the credentials that might appear to be needed. Therefore, he must have credentials from the medical school; he must have a photograph which is identified, signed and sealed by that medical school. Both of these must be viséed by the American consul in the district in which the school is located from which he claims to have graduated. Our law says also that all applicants shall come from schools that have been inspected by a board. Obviously, we cannot inspect these foreign schools. Therefore we say to a man, "You must have American credentials. If you want to enter our state, you must have a year of education in Pennsylvania." We require the intern year regardless of what internship they have had before. After that we require written and practical examinations. The examinations are taken in English. We in the East get a lot of these people. They bring all the influence that they can possibly marshal to bear on our board, but we must be exceedingly careful.

(To be continued)

THE DALLAS SESSION

Diagnostic Clinics at Dallas

A series of diagnostic clinics, similar to those at the last two annual sessions, will be held at Dallas on Monday, April 19. The Local Committee of Arrangements in charge of this important feature of the scientific program has arranged for all necessary clinical material. The clinics will be held in section meeting halls and the detailed schedule will be available for distribution at the Registration Bureau on the opening day of the session.

The general subjects and the names of physicians who have accepted assignments on this program are:

Practice of Medicine—L. F. Barker, Baltimore; Harlow Brooks, New York; Henry A. Christian, Boston.
Surgery—Carl B. Davis, Chicago; Frank H. Lahey, Boston.
Obstetrics—J. O. Polak, Brooklyn.
Ophthalmology—Walter R. Parker, Detroit.
Otolaryngology—George E. Shambaugh, Chicago.
Pediatrics—H. F. Helmholz, Rochester, Minn.
Pathology—C. C. Bass, New Orleans; Francis Carter Wood, New York.
Neurology—L. J. Pollock, Chicago.
Dermatology—Fred Wise, New York.
Urology—Frank Hinman, San Francisco.
Orthopedic Surgery—Philip Kreuscher, Chicago; Arthur Steindler, Iowa City.
Proctology—Jerome M. Lynch, New York.

Extension of Final Limit on Railroad Tickets

The lines of the Southwestern Passenger Association have authorized an extension of final limit of fifteen days with final honoring date, May 12, 1926, on deposit of certificate with joint agent at Dallas and payment of a fee of $1 at time certificate is deposited. Other lines that have authorized similar extension are the Southeastern Passenger Association, the Trans-Continental Passenger Association and the Western Passenger Association. The Central Passenger Association has authorized such extension only from points on the Chesapeake & Ohio and Norfolk & Western railways, east of Cincinnati and Louisville. Only those passenger associations that have made such authorization are mentioned above. It is to be definitely understood that some of the passenger associations have not granted similar extensions.

Teachers of the Diseases of Children

The Association of American Teachers of the Diseases of Children will have its annual luncheon at the Adolphus Hotel in Dallas, Monday, April 19. A meeting of the association will follow this luncheon.

Smoker of Dallas Veterans

Dallas physicians who are veterans of the World War will give a smoker at the Scottish Rite Cathedral at 7 p. m., April 19. An invitation has been extended to General Pershing to attend, and arrangements are being made to have the military band from Fort Sam Houston furnish music for the occasion. Dr. R. L. Van Duzen, 405 Live Oak Street, Dallas, is in charge of arrangements.

Louisville Reunion

The alumni of the Louisville medical schools are planning to hold the largest reunion at Dallas, April 21, ever held in connection with an annual session of the American Medical Association. Dr. Irvin Abell (Louisville Medical College '97), president of the Southern Surgical Association and of the Kentucky State Medical Society, will give an address on "The History and Early Development of Medical Education in Kentucky," illustrated with moving pictures and portraits of Kentucky pioneer physicians. There will be a dinner at the Adolphus Hotel at 7 p. m., followed immediately by the entertainment. Every graduate of the Louisville medical schools is urged to be present and is requested to notify Dr. Charles M. Rosser, president of the Texas committee of Louisville graduates, Medical Arts Building, Dallas, Texas. Tickets will be on sale at the alumni window at registration headquarters.

Special Trains from the East

There will be a special train over the Pennsylvania lines, which will leave New York at 4:50 p. m., April 16, arrive in St. Louis at 5 p. m., April 17, leave St. Louis on the "Sunshine Special" of the Missouri Pacific at 6:45 p. m., April 17, and arrive in Dallas at 1:10 p. m., April 18. A delegation from New England will join the New York party at St. Louis.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Gift of Dr. Musgrave.—The council of the California Medical Association has accepted the gift of Dr. William E. Musgrave of 200 shares of stock of *Better Health* for which Dr. Musgrave paid $20,000 in cash. The council expressed its appreciation of this gift, noting that it exceeds any gift heretofore made to the association.

Annual Report of Medical Examiners.—Six hundred and eighty-four applications for licenses of all classes to practice were filed with the California State Board of Medical Examiners during 1925, and 616 certificates of all kinds were issued by the board, of which 293 were to physicians after a written examination and 264 to physicians presenting qualifications from other states. Illinois again sent to California the largest number of successful applications for reciprocity, and New York the second largest. Only thirty-seven California licentiates obtained reciprocity licenses in other states. Certificates were issued to ten drugless practitioners, ten chiropodists and seventeen midwives, all after a written examination; seventeen licentiates were called before the board for hearings on various charges, ten of them being for violations of the narcotic law. Six licenses were revoked, six were placed on probation and five were pending at the time the report was made. Of the written examinations, the report is said to state that the University of California has not had a failure reported in the last sixteen years.

COLORADO

Anniversary of Laënnec.—About 100 members and guests of the Denver Clinical and Pathological Society commemorated the one hundredth anniversary of the death of Laënnec, February 9, at a dinner at the University Club, Denver. Dr. Gerald B. Webb, Colorado Springs, was the principal speaker. Among the guests were Col. Paul C. Hutton; Lieut. Col. Earl H. Bruns; Major William H. Thearle of the U. S. Army Medical Corps; Dr. George A. Boyd, president-elect of the Colorado State Medical Association; Dr. Maurice H. Rees, dean of the University of Colorado School of Medicine, and Dr. Harry J. Corper of the National Jewish Hospital. Dr. Josiah N. Hall is president of the society.

Clinics at Colorado General Hospital.—The faculty of the University of Colorado School of Medicine, Denver, gave a series of clinics at the Colorado General Hospital, March 23-26, to which personal invitations were extended to every practicing physician in the state. There were clinics in surgery and medicine and in the specialties; also demonstrations in biochemistry, physiology, bacteriology and pharmacology, and clinical pathologic conferences. The program was arranged to afford interest to all groups of practitioners, and to be of practical benefit to those in attendance. Physicians of the state were informed that they are welcome at any time to this institution, which the state provided for teaching purposes.

GEORGIA

Georgia Physician in Hall of Fame.—Having the privilege of memorializing in marble her two most distinguished sons, the state of Georgia will place the statue of Dr. Crawford W. Long in Statuary Hall in the Capitol, Washington, D. C., March 30, at 3 p. m., the eighty-fourth anniversary of Dr. Long's discovery of ether anesthesia. The president of the Long Memorial Association, Frank K. Boland, will preside at the ceremonies, and the daughters of Dr. Long will unveil the statue. Chief Justice Richard B. Russell of the supreme court of Georgia will present the statue to the state, and the governor of Georgia, Clifford Walker, will present the statue to the United States. The speech of acceptance will be made by Senator W. J. Harris of Georgia; Dr. Hugh H. Young of Johns Hopkins University Medical School, Baltimore, will give an address on behalf of the medical profession. Joseph Jacobs, D.Sc., a friend and former employee of Dr. Long, will speak on behalf of the pharmaceutical profession, and Senator George Wharton Pepper of Pennsylvania, on behalf of the University of Pennsylvania, from which Dr. Long graduated in medicine. Responses will be made by Dr. Lamartine G. Hardman, representing the Medical Association of Georgia; by Rebecca Latimer Felton, former U. S. senator from Georgia; by Dr. William Hamilton Long, secretary of the Southern Association of Anesthetists, and by Miss Virginia Gibbes, representing the nursing profession. The Long Memorial Association presented the statue, which was made from Georgia marble by the sculptor, John M. Rhind and carved by James K. Watt. Dr. Long died in 1878 while in attendance on a patient, in whose interest his last words were spoken.

IDAHO

Personal.—Dr. John W. Givens has resigned as medical superintendent of the state asylum at Orofino, which position he has held for more than twenty years.——P. A. Surg. Le Grand B. Byington, U. S. Public Health Service, was directed, February 24, to proceed from Washington, D. C., to Shoshone, and to such other points in Idaho and Montana as may be necessary and return, in connection with an outbreak of Rocky Mountain spotted fever.

CHICAGO

Institute of Medicine of Chicago.—Preceding the March 26 meeting of the institute at the City Club, when Dr. Evarts Graham of St. Louis will speak on "New Developments in Our Knowledge of the Gallbladder," there will be an informal dinner at 6:30; members of the Chicago Surgical Society will be guests of the institute at this meeting. Announcements of future meetings of the institute include two lectures by Sir Arthur Newsholme of London, May 10-11, at the University of Chicago, with which the lectures have been arranged conjointly; Prof. Friederich Mueller of Munich, Germany, in October, 1926; Dr. Francis W. Peabody, Boston, October 29, when the third annual joint meeting with the Society of Internal Medicine will be held, and the seventh Pasteur lecture, November 19, by Donald Van Slyke, New York.

Medical Students Y. M. C. A. Dormitory.—Construction has started on a ten story Y. M. C. A. building to be ereted at Congress and Wood streets, for the exclusive use of professional students attending the medical and dental schools in that locality. The building will be of stone to the third story, and of stone and brick from there to the top. The first floor will house the gymnasium, handball courts and shops. The second floor, club rooms, a cafeteria, offices, lounges, lockers and showers; on the remaining floors will be 365 rooms for students. The building will cost $750,000, of which the students subscribed $50,000, and members of the faculties of various schools, $150,000; it will be completed about December, 1926. The chairman of the committee of management is Dr. Channing W. Barrett. The structure is said to be the first of its type to be erected by the Y. M. C. A.; the design is in harmony with the other buildings in the association's expansion program.

IOWA

Dr. Plass Heads Department of Gynecology.—Dr. Everett Dudley Plass of the Henry Ford Hospital, Detroit, has been appointed head of the department of gynecology and obstetrics at the State University of Iowa College of Medicine, Iowa City, to succeed Dr. Frederick H. Falls, who recently resigned, to accept a similar position with the University of Illinois, Chicago.

Smallpox at Council Bluffs.—There had been 224 cases of smallpox reported at Council Bluffs between Sept. 2, 1925, and March 15, 1926, of which 113 cases were reported in February and twenty-six the first half of March; all have been mild cases with no deaths. Many people are being vaccinated, but the cost to the city of quarantine will exceed many times the cost of a general vaccination program which was advised by the city health officer some time ago.

KANSAS

Health Officer Appointed.—Dr. Shubert D. Henry, formerly of Wichita, Kan., assumed the duties of health officer of Kansas City, March 1, succeeding Dr. Louis B. Gloyne, who resigned to return to private practice, after having served the city as health officer since 1919.

Personal.—George E. Coghill, Ph.D., professor of anatomy, University of Kansas, has been appointed to a newly created chair of comparative anatomy at the Wistar Institute, Philadelphia.——Dr. Edgar M. Sutton, Salina, has been appointed county health officer, to succeed Dr. Samuel T. Blades.——Dr. Enoch C. Wickersham, Independence, has been reappointed county health officer for 1926.

KENTUCKY

Society News.—The Fayette County Medical Society gave a dinner, February 9, in honor of its senior members; Dr. Benjamin F. Van Meter was toastmaster; among the speakers were Dr. Irvin Abell, Louisville, president of the state medical association, Dr. Joseph A. Stucky, Dr. Samuel B. Marks and Judge James D. Denny.

Personal.—At a meeting of the new board of health of Henderson, March 4, Dr. George F. Jones was elected president and Dr. James U. Ridley, city health officer; among the other members of the board are Dr. William V. Neel and Dr. Jesse O. Strother.——Dr. John C. Morrison, who succeeded Dr. James M. Hubbard of Paducah last summer as head of the public health work in the city, has resigned.——Dr. Daniel H. Kash of Jackson has taken up his duties as physician to a coal camp at Blue Diamond.

Physical Defects of Freshmen.—An examination of 837 freshmen by the department of hygiene and public health at the University of Kentucky, Lexington, recently, disclosed, it is reported, that none of them were free from physical defects. Among 512 males, there were defects of the nose and throat in 445, and of vision in 236 among 325 women students examined, 271 had defects of the nose and throat, and 202 defects of vision. Only sixty male students had defective feet; while 101 women students had defective feet, none of them had skin defects; sixteen of the men students had skin defects; forty-two women and sixty-one men had some form of heart disease; only 274 out of the total of 837 had been vaccinated against smallpox within the last five years.

MARYLAND

Influenza Program.—The Baltimore City Medical Society devoted its entire program, March 5, to a discussion of influenza and pneumonia in view of an epidemic of those diseases in Baltimore; among the speakers were Drs. Dean Lewis, Wade H. Frost, Louis P. Hamburger and George W. Mitchell.

Personal.—Of the seven members of the 1876 class of the University of Maryland Medical School, five were present at a reunion to celebrate the fiftieth anniversary of their graduation, February 27, at the Hotel Rennert. Those in attendance were Drs. Wilmer Brinton, Thomas C. Worthington, William E. Wiegand and William H. Marsh, all of Baltimore, and Dr. James F. H. Gorsuch of Fork, Md. Those unable to be present were Dr. Samuel J. Belt, Baltimore, now 82 years of age, and Dr. David W. Smouse, who lives in Des Moines.——Dr. Joseph Goldberger, U. S. Public Health Service, gave an address at the School of Hygiene and Public Health, Johns Hopkins University, Baltimore, March 1, on "Present Status of Our Knowledge of the Etiology of Pellagra."——Dr. John Whitridge Williams, professor of obstetrics, Johns Hopkins University School of Medicine, Baltimore, presided at a meeting of a group of physicians, January 22, which was addressed by Dr. James F. Cooper, of the American Birth Control League, New York, on "Birth Control."——Dr. Daniel S. Fisher has been appointed coroner for the Western district of Baltimore, to succeed Dr. Harry K. Gorsuch, resigned.——Dr. Bernard Philip Herzog has been appointed medical examiner to the board of pension trustees of Baltimore; the other members of the medical staff are Dr. Frank S. Hundley and Dr. Andrew Kunkowski.

MICHIGAN

Society News.—Dr. John K. Ormond of the Henry Ford Hospital, Detroit, addressed the Lenawee County Medical Society, Tecumseh, February 4, on "Diseases of the Kidney, Ureter and Bladder," illustrated with lantern slides.——Dr. John B. Youmans, Ann Arbor, addressed the Calhoun County Medical Society, recently, on "Some Practical Applications of Our Newer Knowledge of the Liver."——Dr. Reuben Peterson of the University of Michigan Medical School addressed the Hillsdale County Medical Society, recently, on "Abnormal Obstetrics."——Dr. Josiah J. Moore, Chicago, addressed the St. Clair County Medical Society, February 4, on "Gallbladder Visualization," illustrated by lantern slides.

Resolution About Laymen Being Health Officers.—The Ingham County Medical Society, Lansing, has adopted a resolution disapproving the address of a member of the American Public Health Association at St. Louis, Oct. 7, 1925, which, it is said, favored a new doctor of public health in every locality where a health officer is needed; it is pointed out that the University of Michigan and the Detroit College of Medicine have inaugurated courses in public health whereby a layman may in a comparatively short time qualify as a doctor of public health and be allowed to practice preventive medicine. The society held the view that all health officers should first be physicians licensed to practice by the board of registration of the state of Michigan.

MINNESOTA

Chiropractors Sentenced.—William F. Wittig and Mathilde C. Andresen, chiropractors of Red Wing, were recently sentenced to thirty days in the Goodhue County jail and fined $50 each for practicing without a license.

University News.—E. F. Burton, Ph.D., department of physics, Toronto University Faculty of Medicine, Toronto, Canada, will lecture at the University of Minnesota, March 30, on "The Physics of the Ultramicroscope: Its Structure and Use, and the Optical Properties of Suspended Particles and Colloidal Cells."

Personal.—Dr. John A. Thabes, Brainerd, has been reappointed a member of the state board of health.——Dr. John T. Bowers has been elected city physician of Thief River Falls, to succeed Dr. Herman W. Froehlich.——Dr. Paul A. O'Leary, Rochester, Minn., has been elected president of the Minnesota Dermatological Society, and Dr. Dale D. Turnacliff, Minneapolis, secretary.

MISSISSIPPI

Governor Signs Antievolution Bill.—Governor Whitfield signed the antievolution bill, March 11, thus enacting a law which prohibits the teaching in state supported schools of the theory that man descended from another form of animal life. The penalty for violation of the law is a fine of from $100 to $500, and revocation of the license of the teacher convicted. This issue is said to have been "injected" into the legislature by organizations outside the state. Within a few minutes after the governor signed the Evans-Hickey bill, a bill had been introduced in the house to repeal the antievolution law.

MISSOURI

License Refused.—Following an investigation, the Hospital and Health Board of Kansas City has refused Dr. Charles O. Ozias a license to conduct a clinic and hospital. Ozias was recently fined $250 for conducting a clinic in Kansas City without a license, it is reported.

Society News.—Dr. John J. R. Macleod, professor of physiology, University of Toronto, Canada, addressed the annual banquet of the Kansas City Academy of Medicine, Kansas City, February 5, on "Some Further Work on Insulin."——The Jackson County Medical Society, Kansas City, will hold a symposium on infantile paralysis, March 30, in which Dr. Frank C. Neff will discuss "The Early Diagnosis and Treatment of Acute Infantile Paralysis," and Dr. Rexford L. Diveley will report on the 1925 epidemic in Kansas City; Dr. Charles S. Williamson, professor and head of the department of medicine, University of Illinois School of Medicine, Chicago, who will be the guest of honor at the fourth annual "president's night," April 6, will speak on "Management of the Simple Anemias."

New Medical School in Kansas City.—A campaign is under way to raise $5,000,000 for a new university in Kansas City to be known as the Lincoln and Lee University. The movement is sponsored largely by the Methodist church, which will elect one half of the members of the board of trustees, and other denominations will elect the remainder. The project is said to be meeting with enthusiasm, particularly among persons interested in the prospect of a school which will have a religious environment. One of the first departments to be established will be the medical department; the trustees contemplate breaking ground this fall, and the beginning of class work one year from that time. The president of the board of trustees is Bishop E. L. Waldorf of the Kansas City District and the Methodist Episcopal church.

NEW YORK

Gift for Study of Children.—An anonymous friend of Vassar College has given that institution $75,000 to erect a demonstration laboratory in connection with the course in eugenics. The laboratory will be used for the scientific study of the care of children from infancy to school age.

Dr. McKay Resigns.—Dr. Florence L. McKay, director of the division of maternity, infancy and child hygiene, state department of health, since 1921, has tendered her resignation, effective at once, on account of ill health, and Dr. Elizabeth M. Gardiner, associate director of the division, has been appointed to succeed Dr. McKay. Dr. Gardiner has been in the state health department for about two years and a half, and formerly was director of the Child Welfare Division of the Rhode Island State Department of Health.

New York City

Dr. Welch Honored.—The Association of the Alumni of the College of Physicians and Surgeons in New York gave a dinner, March 19, at the Waldorf-Astoria, in honor of Dr. William H. Welch, director, School of Hygiene and Public Health, Johns Hopkins University, Baltimore; Dr. Welch spoke on "Reminiscences of the College of Physicians and Surgeons in the Seventies."

"Prescription Bootlegging." — Warrants were issued, March 17, for the arrest of a number of physicians, druggists and distillery salesmen, who were charged with "prescription bootlegging" of a new form in which they are said to have sold their prescription books, signed in blank, to distillery salesmen, who, in turn, sold them to druggists. Testimony obtained after a three months investigation will be presented to the grand jury, it is reported, with a view to indicting a total of about 100 "doctors." A number of those accused have denied the charge.

"Blizzard Class" Reunion.—The thirty-eighth anniversary of the "blizzard class" of Bellevue Hospital Medical College will be celebrated, April 10, at the Hotel McAlpin, 7 p. m. The class, which will again be the guests of their fellow alumnus Dr. David Hunter McAlpin, graduated, March 12, 1888, the date of the memorable blizzard; seventy-five of the 144 graduates are still living; any one of them who has failed to receive an invitation and desires to attend should address the acting secretary, Dr. S. Adolphus Knopf, 16 West Ninety-Fifth Street, New York City.

Society News.—Dr. Richard W. Westbrook addressed the Medical Society of the County of Kings, March 16, on "Blair Bell's Treatment of Cancer with Colloidal Leads"; this society recently received a request for 500 copies of the picture of its new library building from another society, which is planning to build a home.——Dr. George H. Fox, honorary president of the American Dermatological Association, addressed a joint meeting of the West Side Clinical Society and the Washington Heights Medical Society, March 11.——Dr. Louis I. Harris, commissioner of health, addressed the annual meeting of the Mount Sinai Society, March 21, on "The Hospital and Public Health."——Dr. Paul D. White, Boston, addressed the Medical Society of the County of New York, March 22, on "Endocarditis in Earliest Childhood."——Dr. Charles L. Scudder, Boston, addressed the New York Academy of Medicine, March 18, on "When Is Operative Treatment Justified in Fractures of the Long Bones?" and Dr. Joseph A. Blake on "Difficulties in Reduction of Fractures in Long Bones and the Principles of Treatment"; Dr. James M. Hitzrot on "The Cause of Nonunion," and Dr. William Darrach on "Fractures in the Aged, Their Prognosis and Treatment."——Dr. Dennett L. Richardson, director, City Hospital, Providence, R. I., addressed the Yorkville Medical Society, March 15, on "Care and Hospitalization of Infectious Diseases."—Dr. Dean Lewis, professor of surgery, Johns Hopkins University Medical School, Baltimore, addressed the Brooklyn Surgical Society, March 4, on "Sarcoma of Bone," and was the guest of honor at a dinner and reception.——Dr. Harry E. Stewart, New Haven, Conn., was elected president of the New York Electrotherapeutic Society, March 3, and Dr. Charles R. Brooke, Newark, N. J., secretary.

OHIO

Another "College President" Indicted.—Solomon L. Long, head of the "College of Anatomical Science" at Cleveland, was indicted, March 9, by the county grand jury, having been charged, following an investigation by the state medical board, it is reported, with issuing a "false medical diploma," conferring the degree of "doctor of anatomical science." Prior to coming to Cleveland, Long is said to have conducted a school in Fort Wayne, Ind.

Impostor's Patient Dies of Lead Poisoning.—The state medical board of Ohio recently caused the arrest of William H. Young at Gallipolis, who, it is reported, had been treating a patient for varicose ulcers by means of an ointment and plasters that contained lead. The patient, who was eventually removed to a hospital, died, and the cause given in the death certificate was lead poisoning. Young is said to have obtained about $1,500 from the family. He is not a practitioner of medicine and has no certificate to practice in Ohio; he was bound over to the grand jury on a charge of manslaughter.

PENNSYLVANIA

Typhoid Fever Epidemic at New Milford.—Fifty cases of typhoid fever and three deaths were reported at New Milford, March 12. The American Red Cross had sent ten nurses to the village (the population is about 600) and other nurses were obtained from Scranton, and from Binghamton, N. Y. With one exception, the victims are under 30 years of age. The water supply is said to account for the epidemic.

Endowment for Henry Phipps Institute.—The trustees of the University of Pennsylvania have accepted the offer of Mr. and Mrs. Henry Phipps, New York, to assist in creating an endowment for the Henry Phipps Institute by which they will give $500,000 on condition that the university raises a like amount before Jan. 1, 1927. On fulfilment of this condition, all buildings and equipment belonging to the institute will be deeded to the university. Further plans by the university are for the gradual accumulation of funds allotted to the institute in its campaign to raise $45,000,000 over a term of fifteen years, so that when the campaign is successfully completed, the Phipps Institute will have an endowment of $2,300,000. The institute was placed under the care of the University of Pennsylvania in 1910, Mr. Phipps supplying the funds to maintain the work until 1919, and partly since that time in conjunction with the university, the Carnegie Corporation and the Welfare Federation of Philadelphia. While the institute was founded for the study, treatment and prevention of tuberculosis, provision is made in the plan for endowment that when further study of tuberculosis is no longer pressing, the income of the endowment may be used for the study of other diseases. The directors of the institute now are Drs. Charles J. Hatfield, Eugene L. Opie and Henry R. M. Landis. There has never been an endowment for the Henry Phipps Institute.

Philadelphia

Personal.—Dr. George A. Ulrich has been appointed chief visiting obstetrician to the Northwestern General Hospital. ——At the eighteenth annual business meeting of the Pennsylvania Conference of Social Welfare, Dr. Isaac M. Rubinow was elected president for 1927.

Society Dedicates New Home.—The Philadelphia County Medical Society will dedicate its new home, April 21, with exercises at 2 o'clock, and final dedicatory exercises at 8: 30 p. m The next evening at 8·30 will be ladies' night, when there will be a reception, musicale and dance; the building will be open for inspection both days of the celebration.

RHODE ISLAND

Hospital News.—The new $150,000 South County Hospital, Wakefield, was recently dedicated. Facilities have been provided for twenty-two beds at present, and the building will accommodate almost twice that number of patients.

Society News.—Dr. James F. Cooper, New York, of the American Birth Control League, addressed the Washington County Medical Society, Westerly, recently on "The Technic of Contraception."——Alonzo R. Williams, Esq., Providence, addressed the Rhode Island Medico-Legal Society, recently, on "The Medical Man on the Witness Stand."——The program of the Providence Medical Association February meeting was devoted to medical education; addresses were made by Dr. Samuel R. Meaker, Harvard University, on "The Postgraduate Medical Education"; Dr. Alexander S. Begg, dean and Waterhouse professor of anatomy, Boston University School of Medicine, on "Undergraduate Medical Education," and Frank G. Wren, A.M., of Tufts College, Medford, on "Premedical Education."——Dr. Jeffrey J. Walsh, Providence, has been elected president of the Rhode Island Ophthalmological Society.

WASHINGTON

Sanipractors and the Referendum.—John E. Lydon, former president of the defunct American University of Sanipractic of Seattle, is circulating a petition to obtain signatures to file with the secretary of state, for a referendum on a broader recognition of sanipractic in Washington at the November election. The sanipractic bill was defeated recently in the legislature. Should it become a law by referendum, the licenses of about ninety sanipractors, which were revoked because of fraud in connection with the diploma mill exposé, would be restored; there would be a separate board of examiners for sanipractors, and the examinations would be conducted by the secretary of state instead of by the director of licenses who now conducts such examinations. It may be recalled that John E. Lydon's "university business" grew so rapidly and the complaints of selling diplomas became so numerous that the state instituted proceedings to dissolve his school. The court ordered the university closed. A law was then passed which made it possible to revoke the licenses of about ninety sanipractors which were said to be fraudulently obtained. Lydon recently presented two bills to the legislature, and both of them received unfavorable reports in committee. He is now trying to obtain a referendum.

WISCONSIN

Personal.—Dr. and Mrs. Joseph Schneider, Milwaukee, gave the Milwaukee University School $50,000 in February to be applied on the new building.——Dr. Robert D. Millard has taken up postgraduate work at the Wisconsin General Hospital, Madison, following three years spent in Honolulu.—— Dr. Stephen Cahana and Felix J. Baur have been appointed fire department physicians of Milwaukee.——Dr. Otho A. Fiedler, Sheboygan, has been reelected president of the state board of health, and Dr. Cornelius A. Harper reelected as state health officer.

GENERAL

Fund to Encourage Pharmaceutic Research.—The American Pharmaceutical Association has available a fund of $450, which will be expended after October 1 for the encouragement of research. Investigators who desire financial aid in their work should communicate with the chairman of the research committee, H. V. Arny, 115 West Sixty-Eighth Street, New York, before June 1, giving their record and outlining the line of work for which the grant is desired.

Fatalities in Coal Mines.—According to the bureau of mines, 318 men lost their lives in January on account of accidents in coal mines in the United States. This unusually large total was due to four major explosions, the most disastrous one being that of Wilburton, Okla., January 13, in which ninety-one men were killed. Another occurred at Farmville, W. Va., January 14, killing nineteen men; another at Frankfort, Ill., January 29, killing five men, and another at Helena, Ala., January 29, killing twenty-seven men. There were more than 1,000 men in the mine at Frankfort when the explosion occurred, and the death of only five is attributed to the use of rock dust, which localized the effects of the blast.

New County Society Presidents.—The following physicians have recently been elected president of the county medical society indicated:

Dr. John T. Anderson, Warrensburg, Mo., Johnson County Medical Society.
Dr. Louis Bagby, Vinita, Okla., Craig County Medical Society.
Dr. Charles G. Baird, Beatrice, Neb., Gage County Medical Society.
Dr. Alonzo W. Benton, Neosho, Mo., Newton County Medical Society.
Dr. William W. Bolster, Lewiston, Me., Androscoggin County Medical Society.
Dr. Edward T. Bramlitt, Malvern, Ark., Hot Spring County Medical Society.
Dr. Thad Cothern, Jonesboro, Ark., Craighead County Medical Society.
Dr. Robert L. Crawford, Locust Grove, Ga., Henry County Medical Society.

Dr. Rennie Wright, New Braunfels, Texas, Comal County Medical Society.

Bills to Standardize Clinical Thermometers.—Prospects for legislation to standardize clinical thermometers at the present session of Congress are uncertain because proponents of this legislation do not agree on the details of pending bills. A hearing was held by the Senate committee on interstate commerce, March 4, on two bills introduced by Senator Royal S. Copeland, New York, to regulate interstate commerce in the traffic of clinical thermometers. The first bill provides that all thermometers sold in interstate commerce should be tested by the bureau of standards at Washington. The objections to this measure are that it imposes undue hardship on reputable manufacturers of clinical thermometers and would increase the cost of thermometers, as a reasonable fee would be paid by the manufacturer to the government for such tests. The manufacturers would have to bear, too, the expense and losses incident to shipment to and from the government testing laboratories. The second bill would regulate the standard of clinical thermometers by requiring manufacturers to secure from the secretary of commerce licenses or permits, which would be issued after the inspection of the plants and factories to ascertain "the ability of the manufacturers to promote and to promulgate the rules and regulations" fixed by the bill. Dr. William C. Woodward, Chicago, secretary, Bureau of Legal Medicine and Legislation of the American Medical Association, stated to the committee that that organization favored the principles of the bill providing for the licensing system; he did not unqualifiedly approve the measure, however, indicating that it should be redrafted to overcome obscurities apparent in its phraseology; among others who made statements before the committee were Dr. W. P. Morrill, Washington, D. C., representing the American Hospital Association; Mr. G. P. Faichney of the Faichney Instrument Corporation, Watertown, N. Y., and Mr. M. W. Becton of the Becton-Dickinson Company, Rutherford, N. Y. It was the opinion of all witnesses that methods should be devised by legislation to provide that clinical thermometers be of the highest quality. It was clear, however, from the testimony presented that there is a wide difference of opinion as to the best methods to bring about such results. The committee adjourned with the feeling that no legislation is likely to be enacted until medical authorities and manufacturers can reach a general agreement on definite methods of legislation.

PHILIPPINE ISLANDS

Personal.—Major Arthur Parker Hitchens, M. C., U. S. Army, a member of the army medical reserve board in Manila, has been detailed as technical adviser to the governor general in matters of public health.

Society News.—The Philippine Islands Medical Association has petitioned the University of the Philippines to renew the grant of 600 pesos made to the association's journal, and, if possible, to make it of permanent character; the association at its last annual business meeting in Manila voted to request the legislature to appropriate funds for the control and eradication of trachoma. The association voted at the business meeting in Manila in December to table the report of the special committee appointed to study the advisability of securing the independence of the Philippine Islands' Medical Association.

FOREIGN

Scientific Congresses in Germany.—The annual meeting of the German Association for Internal Medicine is to be held at Wiesbaden, April 12-15, with the usual annex exhibition. The topics appointed for discussion are "Neurosyphilis"; "The Blood as Mirror of Somatic Processes," and "Asthma." It is to be followed by the first general medical congress on psychotherapy. The German Surgical Congress convenes at Berlin, April 7-10, and is to be followed by the Roentgen Congress, with Dr. M. Haudek, Vienna, in the chair. The themes for discussion are "Postoperative Irradiation," "Visualization of the Gallbladder," and "Dosimetry of the Roentgen Rays."

British Medical Association Meeting.—The ninety-fourth annual meeting of the British Medical Association will be at Nottingham in July under the presidency of Dr. Frederick G. Thomson; July 16, the annual representative meeting will begin and continue the three following week days. The representative dinner will take place at the Victoria Hotel, July 16; the statutory annual general meeting, July 20; the annual dinner of the association, July 22; the conference of honorary sections, July 21; the official religious service at St. Mary's Church, July 20; a popular lecture will be delivered by Prof. Leonard Hill in the evening, July 21; and July 24 will be given up to excursions to places of interest in the neighborhood. The incoming president, Mr. Robert G. Hogarth, will deliver his address, July 20. The scientific sections will meet from 10 a. m. to 1 p. m., July 21-23.

CORRECTIONS

Philadelphia Neurological Society.—The new officers noted in The Journal, March 20, under Philadelphia Society News were elected by the Philadelphia Neurological Society instead of the Philadelphia Urological Society.

Dr. Mary Putnam is Not Dead.—The notice of the death of Dr. Mary Putnam, 124 East Fifty-Fifth Street, New York, published in The Journal, March 20, was an error, and Dr. Mary Putnam is alive and well. It was Dr. Mary S. Putnam of New York and formerly of Battle Creek, who died February 16.

The Causation of Cancer

"An Investigation into the Statistics of Cancer in Different Trades and Professions" has been published by the Medical Research Council. The inquiry was carried out by Dr. M. Young and Mr. W. T. Russell, working in collaboration with Dr. John Brownlee (director of statistics of the Medical Research Council) and Dr. E. L. Collis. They examined the records of more than 46,000 cases of death from cancer in 160 different occupations, and state that this is "a survey of the relation of cancer to occupation with a detail beyond any hitherto attempted." The group of open-air workers, including agricultural laborers, seamen in the merchant service, dock laborers and railwaymen, was found well in the front in excess of cancer of the lip. Among these, cancer of the lip is from 200 to 300 per cent in excess of what might be expected. In the next degree, having about 60 to 100 per cent in excess of the normal amount of lip cancer, are masons, laborers in general, farmers and graziers. These open-air workers have in common unrestricted opportunities for indulging in smoking, and the probability exists that twelve or fourteen years ago cheap clay pipes were favored. Coal miners working below ground, where smoking is prohibited, contrast with colliery workers above ground in not suffering any excess of lip cancer. The mortality from cancer of the lip is thirteen times and of the tongue eleven times higher among men than among women.

Alcohol appears as a predisposing cause of cancer of the tongue and esophagus. Among the groups in which cancer of this part is in excess of the average are brewers, porters, dock and wharf laborers, costermongers, hawkers and butchers, "who are supposed to consume an excessive amount of alcohol." Occupations with unusually low incidence of cancer of the tongue do not include any group with a high death rate from alcoholic diseases. But excess of cancer of the tongue is also found among slaters, tilers, cutlers, printers and plumbers; and it is said that the habit of drinking very hot tea, boiled over a fire for the mid-day meal, may furnish an explanation. Among men who have an excessive amount of cancer of the esophagus are those engaged in the liquor trade: brewers, publicans, inn and hotel keepers, beer bottlers and cellarmen, as well as commercial travelers, coachmen and cabmen, horsekeepers and grooms, and others who are supposed to consume an excessive amount of alcohol. There is thus very suggestive, if not practically conclusive, evidence that excessive consumption of alcohol predisposes to cancer of the esophagus.

The stomach is the most frequent site of cancer in men, and the disease occurs in excess among miners, quarriers, and in certain occupations in the manufacture of wool and cotton. Cancer of the larynx is high in musicians, army officers and law clerks, while cancer of the bowel is significantly above the normal in barristers, solicitors, bankers, bank clerks, teachers, commercial clerks, clergymen and others of sedentary occupation.

Medical Officialdom: Eleven Physicians to One Family

Eleven official physicians for one family is a possibility under the present system of public health services, according to the British Medical Association. A memorandum of the evidence to be given to the royal commission on local government says that the chaos and wastefulness of health administration are made worse with every act of parliament that is passed dealing with these matters. In the extreme but possible example of a poor family with one mentally defective child living in a noncounty borough, the following medical officers might be interested at the same time: the county medical officer, with his tuberculosis officer and mental deficiency officer; the borough medical officer; the maternity and child-welfare officer; the school medical officer or officers of possibly two education authorities (county and borough); the insurance practitioner or practitioners; the poor law medical officer or officers; the special physician for the treatment of venereal disease, and a special smallpox officer.

The mother of such a family will usually be attended at childbirth by a midwife, who in an emergency must call on the services of a physician (either private or the poor law medical officer). Notification that this has been done must be made to the medical officer of the county; the birth must be notified to the medical officer of health of the borough, and registered with the registrar. The house will be visited by the inspector of midwives, by the sanitary inspector, by the health visitor, by the vaccination officer, by the infant life protection visitor, by the school nurse, by a visitor under the mental deficiency act, possibly also by the relieving officer and by semiofficial or unofficial but kindly persons (as, for example, district nurses) interested in the health and well being of its inmates. When a poor patient has to go to a hospital or elsewhere there is a similar chaotic and expensive state of affairs. The many institutions are established and conducted as independent units unrelated to one another. The remedy suggested is the creation of new large health administrative areas, each controlled by a local health authority with full administrative powers, and a medical committee, elected by local physicians, to appoint representatives on the local health committee.

Military Hospital Reserve

The reorganization of the "home hospitals reserve" under the designation of the "military hospitals reserve" has been approved by the war office, and the qualifications for enrolment are stated in an army order. This reserve will consist of warrant and noncommissioned officers and privates only, with an authorized establishment of 2,000. The functions of the reserve will be (*a*) to staff the military hospitals and other establishments maintained by the regular medical services on the mobilization and withdrawal of the regular royal army medical corps for duty in the field; and (*b*) to provide reinforcements for the medical units of the expeditionary force overseas after mobilization. Membership will be entirely voluntary, and the personnel will be provided by the St. John ambulance brigade for England and Wales and northern Ireland and the St. Andrew's ambulance corps for Scotland. The age limits for enrolment will be from 19 to 40 years, and no member will be permitted to remain in the reserve after he has reached the age of 45 years. Every applicant must be in possession of the first-aid certificate recognized or granted by the St. John ambulance association, and, in addition, obtain a nursing certificate recognized by those bodies within a period of twelve months after enrolment. A proportion of the total establishment of each rank in the reserve will, in annual rotation, receive training for eight days under military arrangements. Training will be undergone in a military hospital or other military medical establishment, and as far as possible a member will be detailed for this purpose to the hospital to which he would be posted on mobilization.

Fewer Women in Medicine

Lord Sands, who presided at the annual meeting of the Carnegie trust at the universities bureau, said that although since the immediate postwar years there had been a great increase in the numbers of students in arts, as a result of the increased remuneration for teachers, in science and medicine the boom of 1920 had moved to the opposite extreme in the case of women students, for there had been a considerable measure of disillusion in regard to postwar expectations of openings for women in these professions. In medicine the number of women students was 484 in 1920, whereas the number was 101 in 1925. There was apparently a further fall this year.

The Proposed Irish Free State Medical Register

The question of a separate medical register for the Irish free state has been discussed in previous letters. Mr. R. C. B. Maunsell, president of the Royal College of Surgeons in Ireland, announced at the annual meeting of the Incorporated Orthopaedic Hospital in Dublin that, Dec. 21, 1925, three physicians were appointed as a subcommittee to discuss proposals with the free state government for a permanent arrangement with the general medical council, but since that date they had not been approached or consulted. Meanwhile, arrangements had been made for a continuance of the present system until the end of the present year, but the absence of a permanent settlement was driving medical students out of the country, and the Rockefeller Foundation had decided to break off negotiations with the free state medical profession concerning a substantial grant of money for the amalgamation of at least five Dublin hospitals.

Deaths from Septicemia Contracted in Performing Postmortem Examinations

The Cambridge Medical School has suffered the loss of a brilliant young teacher under circumstances that recall the death in January of Miss C. Iris Fox, senior assistant pathologist at the Royal Free Hospital. She died from septicemia contracted during a postmortem examination. That was also the cause of the death of Dr. M. B. R. Swann, fellow of Caius College at Cambridge, and university demonstrator in pathology.

Birth Control in Parliament

In the house of commons, Mr. Thurtle, a labor member, asked leave to present a bill to authorize local authorities to incur expenditure, when deemed expedient, in conveying knowledge of methods of birth control to married women who desired it. His purpose was to make known to very poor women information which would enable them to restrict their families, such as was at present utilized by wealthier women. Year after year the falling off in the birth rate became more and more marked in the upper and middle classes, while in the poorer classes it was almost stationary. In districts where overcrowding was most rampant and poverty most acute, there was a very high birth rate. We were spending money in broadcasting information about sanitation, personal hygiene, diet, tuberculosis and venereal disease, solely on the ground of maintaining public health, and there was not a phase in the work that was not rendered more difficult by women in the poorest districts having larger families than was good for themselves or for the state.

Another labor member, Rev. J. Barr, opposed the motion. The ignorance of poor women on the subject which the bill dealt with was, he said, greatly exaggerated. He desired that the very best medical information and skill should be brought to the doors of the very poor, but that was quite different from entering on a national policy of birth control and propaganda. Economically, it was a policy of despair. He believed that a bountiful creator had provided ample resources for all if there was wise production and just distribution. Moral instincts and religious prejudices—call them what they would—were, after all, the purest, finest and most potent influences in the uplift of mankind. In such questions they were as sure a guide as science itself, and if we chose to defy them we did so at our own peril and the peril of the state. The bill was rejected by 187 votes to 81.

Functions of Region About Infundibulum and Tuber Cinereum, and Its Relation to Pituitary Body

Gustave Roussy, to whom we are indebted, along with Camus, for important researches on the functions of the infundibulotuberal region, contributes an excellent article on the subject in a recent number of the *Annales de médecine.* Pierre Marie was the first (in describing acromegaly) to call attention to the rôle of the pituitary body. The history of the gland may be divided into two main periods: First, the physiologic importance of the pituitary body was established experimentally by Harvey Cushing, Bield and Marañon. Since the researches of those authors, we speak of syndromes of the anterior lobe and syndromes of the posterior lobe, and the hypophysis has occupied a place of first rank in the physiology of the endocrine glands. Second, beginning in 1911 with the researches of Aschner, Camus and Roussy, there has been a tendency to limit the number of functions attributed to the pituitary body, or, more particularly, to the nervous lobe, and to attach the functions thus dispossessed to the series of nuclei in the gray substance of the floor of the third ventricle.

The experimental data on which Camus and Roussy based their conclusions are given in detail in their communication presented at the International Congress of Neurology held in 1922. In the course of their researches they experimented with 149 dogs and forty-six cats. In some instances they removed the hypophysis by the parietal or palatine route; in other cases they induced lesions in the infundibulum and tuber cinereum by piercing the palatine velum with a red-hot drill. One primary fact brought out by the experiments was that, contrary to the view held by other authors, the hypophysis is not indispensable to life. It is true that many animals operated on die, but mere puncture of the region of the infundibulum and tuber cinereum, with the hypophysis left intact, is just as fatal. Furthermore, several animals survived for a long time the complete removal of the hypophysis as verified at necropsy.

Harvey Cushing was the first to call attention to the polyuria resulting from operations on the hypophysis, and particularly on the posterior lobe. In 1913, Camus and Roussy showed that polyuria could be caused by wounding the region of the infundibulum and tuber cinereum alone. In operations for the extirpation of the hypophysis, polyuria is occasionally observed, but only when, during the operation, a lesion of the tuber cinereum region is effected. If the tuberal region is injured, while the hypophysis remains intact, polyuria is always induced, sometimes of a transient character, and sometimes more or less permanent, amounting thus to diabetes insipidus. Studies seem to indicate that the injured region forms part of a regulatory mechanism controlling micturition. Sometimes, polyuria and polydipsia are concomitant; at other times, polyuria is observed without polydipsia. A lesion of the base of the brain never causes polyuria in young animals, which would seem to indicate that the centers concerned are not sufficiently developed in young animals. Experimental polyuria sometimes amounts to from four to six times the normal quantity. Sometimes it occurs the first day and, in other cases, from the fourth to the tenth day.

In the experiments of Camus and Roussy, experimental glycosuria, which to some investigators has seemed an essention finding (Aschner), was rarely found and, when it did occur, it was of a transient character. Its occurrence, however, indicates a different regulatory mechanism for the metabolism of carbohydrates, not in the posterior lobe of the hypophysis but in the floor of the third ventricle. Removal of the hypophysis, when accomplished without injuring the base of the brain, does not cause atrophy of the genitalia nor modify their functions. However, with certain experimental lesions of the base of the brain, the authors observed genital atrophy in dogs, or, at least an arrest of development and suppression of libido. In several instances, following experimental lesions of the base of the brain, the authors noted undue increase of adipose tissue. Such obesity is sometimes sudden and marked. Genital atrophy associated with obesity constitutes the classic syndrome described by Babinski and Froehlich. The syndrome may be combined with diabetes insipidus and be of a permanent character, but never did the mere removal of the hypophysis produce such manifestations.

For some time it has been admitted that injection of pituitary extract will induce polyuria (Schäfer and Magnus, 1901), the "polyuric substance" being contained in the posterior lobe. The substance, coursing through the blood, acts directly on the secretory renal cells, independent of any vasomotor action.

Removal of the posterior lobe of the hypophysis causes no appreciable injury. Furthermore, Camus and Roussy observed experimentally that occasionally injection of pituitary extract, instead of stimulating, may depress micturition. The selective rôle of pituitary extracts remains therefore to be demonstrated. The effect of experimental lesions of the base of the brain on the general development of the animal is not fully established as yet. Development seems to be a function of the anterior lobe of the hypophysis, for the action of that lobe on the development of the skeleton appears to be great.

Microscopic study of experimental specimens by Camus and Roussy enabled them to affirm with still greater confidence that the polyuric syndrome is not induced by a hypophysial lesion but by a superficial lesion of the region of the tuber cinereum. Such lesions affect the nuclei of the tuber cinereum, chiefly in their middle and anterior portions.

The authors have not been able as yet to localize definitely the centers which, when injured, cause glycosuria and adiposogenital disorders. In recent years, Camus and Legrand have again been studying the question of the glycosuric center by experimenting on rabbits. From their researches, they conclude that experimental glycosuria in the rabbit, which is irregular, usually tardy in appearance and sometimes prolonged, is produced by a lesion of the paraventricular nucleus located on each side of the wall of the third ventricle within the anterior pillar of the trigon. A number of anatomic and clinical observations have thrown light on the experimental questions. They have observed, for example, several cases of polyuric syndromes following inflammatory or neoplasic processes at the base of the brain, while the hypophysis remained intact (syphilitic or tuberculous meningitis, epidemic encephalitis or possibly traumatism).

The researches described have tended to dispossess the hypophysis of some of its supposed functions and to bestow them on the tuber cinereum. The rôle of the anterior lobe in the growth of the skeleton, and in dwarfism and gigantism, remains incontestable. Of late, researches have been made on the mechanism of experimental polyuria. It has been shown that polyuria occurs even after denervation of the kidney. The nervous system, therefore, has nothing to do with the production of experimental polyuria.

Researches have been made to discover whether substances circulating in the blood might cause the phenomenon. It has been observed (Bailey and Bremer) that if a polyuric animal is given an extra amount of sodium chloride in its food, the polyuria is much more marked than otherwise. That is especially true of polyuria following a lesion of the tuber cinereum.

Camus and Gournay have endeavored to produce polyuria in normal dogs by injecting into them the blood or urine of polyuric animals, or even by transfusing into them, by cross circulation, the blood of polyuric animals, but the experiments gave only negative results. The same authors have observed also that, while all the other substances eliminated in the polyuric urines were merely diluted, the phosphates and the purine bases were considerably increased, sometimes in the proportion of 30 to 1. The authors then injected purine bases (guanine, adenine, hypoxanthine) into normal dogs subcutaneously or intravenously, thereby inducing, according to the amount injected, either a transient polyuria or diabetes insipidus of long duration. Their experiments indicate that modifications in the elimination of decomposition products of nucleoproteins may explain the mechanism of experimental diabetes insipidus. Such an assumption meets with objections, and the question must be studied further.

Researches of great interest have recently been carried out in Nancy by Professor Collin on the histophysiology of the hypophysial secretion. His researches tend to show that the hypophysis exerts an influence on the function and nutrition of important centers located at the base of the brain. Collin has shown also that the colloid that exists in the anterior lobe, in the pars intermedia, and in the interstitial tissue of the posterior lobe may be traced along the wall of the infundibulum up to the immediate vicinity of the nerve cells of the tuber cinereum. We may conclude from that fact that the "neuro-endocrine" secretion plays a very important part in the functioning of the centers found to exist at the base of the brain.

The Medical Examination of Railway Employees

Medical examination of railway employees was recently discussed before the Academy of Medicine. Professor Guillain emphasized the necessity of examinations at intervals of five years for young persons and of three years for elderly employees. Especially neuropsychiatric and cardiologic examinations should be more frequent. Employees whose duties affect the public safety—particularly locomotive engineers—should undergo ophthalmologic examination every two years. Engineers subject to alcoholism should be dismissed at once.

Professor de Lapersonne pointed out that among railway companies there was no uniformity in ophthalmologic examination and that the examination itself left much to be desired. Examination of vision should be very precise and should include color tests. The best method of examining an engineer would seem to be while performing his duties on his engine. When it is impossible to examine an engineer actually on duty, apparatus could be employed which would simulate actual conditions. Promptness in recognizing signals is an important factor, for an engineer may have to react to 200 signals on a 100 kilometer run, while going 80 kilometers an hour.

Functional examination of the pupils is very important. Some railway systems have only one ophthalmologist, to whom only doubtful cases are submitted. The ordinary examinations are made by the physicians of the companies, who, while they may be competent practitioners, have not the skill of specialists.

M. Guillain read a letter from the federation of railway workers which pointed out the financial straits to which dismissal would reduce them. The academy declared that their sole duty was to recognize diseases which might cause accidents.

RIO DE JANEIRO

(From Our Regular Correspondent)

Feb. 15, 1926.

Hemilaryngectomy

Dr. Souza Mendes recently reported to the Medical and Surgical Society a case of hemilaryngectomy, the first time this operation has been performed in Brazil. The patient, aged 56, had for more than twenty years a masked form of goiter, and suffered from a prickle cell carcinoma in the left vocal cord. Gluck and Soerensen's technic was used, with local anesthesia. Healing was by first intention, and the patient was discharged on the twelfth day following the operation. Dr. Souza Mendes discussed incidentally the excellent results secured by him and Dr. D. de Sanson in several total laryngectomies. He explained the successful outcome and benign course in such cases through the great humidity and high temperature in Rio. These seem to block rather effectively postoperative pneumonia, so frequent in Europe in such cases.

Progressive Muscular Atrophy

Prof. Henrique Roxo exhibited before the Society of Neurology and Legal Medicine a case of progressive muscular atrophy with mental degeneration. Since infancy there had been a perverse tendency, which toward puberty took the form of sexual perversion. After suffering four years ago from headaches, fever and convulsions, muscular changes developed, with atrophy of the thenar and hypothenar prominences and claw hand in the right upper extremity. There is also marked atrophy in the muscles of the forearm, arm and shoulder. The opposite arm shows decreased thickness and energy, but the forearm and hand have remained so far normal. The right lower member is completely atrophied, but the left leg is perfectly normal. Sensation seems normal; there is weakening of the tendon reflexes; there is lack of response to faradic excitation, but a positive galvanic reaction; Nonne's test is negative. Roxo contrasted the features of infantile paralysis and Duchenne-Aran's progressive muscular atrophy. His patient has the peculiarity that while the atrophy began typically enough in the hand in one side, it has started in the upper arm in the other extremity. The type seems also uncommon, because of the presence of degeneration.

Industrial Sanitation

In discussing the subject of industrial medicine before the Brazilian Society of Public Health, Dr. J. de Barros Barreto referred especially to American methods and practices, describing his observations in a number of workshops visited by him in the United States. He discussed the employment of patients with tuberculosis and heart disease, preventive training in industrial safety, free medical first aid and dental clinics for workers, and the rôle of visiting nurses in industry. Barros Barreto stressed the value of periodic health examinations from the standpoint of the workers. He also showed the need of placing this work in the hands of experts. In concluding, plans were sketched for introducing industrial hygiene work in Brazil.

Neurorelapse

Dr. G. de Moura Costa reported to the Society of Neurology, Psychiatry and Legal Medicine a case in which the patient received at first two injections of neo-arsphenamine. Fifteen days afterward, headaches and right peripheral facial paralysis appeared. The interesting part was the enormous cerebrospinal lymphocytosis, 3,160 per cubic centimeter, probably the highest on record, as Van Haecke found only 2,400; Benario, 2,000; Dreyfus, 1,600; Zealoziecke, 1,500, and Jeanselme, 900. After an arsphenamine course, with a total dosage of 7 Gm., all symptoms disappeared, and the cerebrospinal fluid became normal. A neurorelapse is always proof of insufficient arsenical treatment. Among approximately 800,000 injections of mercury, Moura has never seen a single nerve relapse.

Public Health Courses

The law reforming medical teaching in Brazil created a special postgraduate course in hygiene and public health for physicians. Those completing the course become eligible to positions under the federal public health service, without having to pass the usual examination. The course is given in the Oswaldo Cruz Institute, under the supervision of the dean of the medical school. It includes: general epidemiology and prophylaxis; organization of special preventive measures; applied biometrics and statistics; food hygiene and bromatologic essentials; urban and rural sanitation; prenatal care, infant hygiene and school sanitation; professional and industrial hygiene; public health administration, and legislation. The course lasts a whole year. As a prerequisite for enrolment, an M.D. degree and completion of a course in microbiology in the Oswaldo Cruz Institute (or its equivalent as proved by examination) are essential.

Personal

At the invitation of the Paris and Berlin universities, Prof. M. Couto, president of the National Academy of Medicine and the most prominent Brazilian clinician, has left for Europe to deliver several lectures.

BERLIN

(From Our Regular Correspondent)

Feb. 13, 1926.

Swimming Pool Conjunctivitis

In the Berliner Verein für Schulgesundheitspflege, Prof. Dr. Comberg of Berlin discussed swimming pool conjunctivitis. It was first observed in Berlin in 1899. In 1919 forty-six cases developed among patrons of the Neukölln city baths. The disease manifests itself in the following manner: A few days after exposure in the swimming pool, one eye becomes red and swollen. This condition is accompanied by lacrimation and a slight narrowing of the palpebral fissure. The follicles of the lower lid are swollen, and, in severe cases, the same condition occurs in the upper lid. Only the conjunctiva is affected. Ulcers do not occur. The infection lasts usually only a few weeks, yielding to treatment. Patients are often unaware of the condition. In 1919, of 250 bathers at the Neukölln swimming pool, Comberg found ten affected with the disease, unknown to themselves. Since 1919, 416 cases have been observed. However, during the last nine months, prophylactic measures have been instituted in all the swimming pools of the city, and no new cases have developed, although recurrences in former patients have been noted.

Prof. Dr. Seligmann of Berlin discussed the prophylactic measures that have been employed. Daily treatment of the water with chlorine gas has been effective. Every few days, the water of the pools is subjected to a chemical, bacteriologic and biologic examination. In addition to disappearance of the conjunctivitis, an indirect hygienic advantage is that it is now unnecessary to change the water daily. This saves time and money, so that the price of baths has been reduced.

Distribution of Age-Groups in Germany

"The war and, to no less extent, the inflation of the currency have left their fatal mark on the distribution of age-groups in Germany, and one of the principal tasks of the interpreter of the figures of the last general census is to explain the probable effects of future adjustments," writes Oberregierungsrat Roesle in the *Deutsche medizinische Wochenschrift*. He emphasizes the reduced percentage of children under 10 years of age and because of war losses of men between the ages 26 and 45. To be sure, there is a reserve force in the men and women born between 1900 and 1914, who now constitute the 11-25 age-group, and who represent a larger percentage of the total population than the corresponding group did in 1910. It is, however, doubtful whether the 11-25 age-group, which, during its physical development, suffered from the exigencies of war and which, in the coming years, will bear the burden of the peace treaty, will develop greater fertility than the present group that is passing through the productive stage of life. Roesle thinks it probable that, in view of prospective burdens, they will restrict the number of their children.

Those who do not find an opening or who demand better living conditions than their environment promises them, emigrate to other lands. Therefore Germany, since the war, has again become a migrating nation, and, from all appearances, will remain such until the age-groups weakened by the war and postwar inflation have taken their places in the economic and industrial life of the country. This, however, will not be before 1930.

The modifications in the age distribution of Germany's population influence the mortality rates. German mortality rates since 1921 have been the lowest ever recorded. One of the most important causes is the changed age distribution of the population. With the decrease in the number of births, there has been a decrease in the number of children dying. At the same time, the life expectancy of children has increased greatly. In 1924, the proportion of deaths among children under 1 year of age was only 18.7 per cent of the total number of deaths, as compared with 26.4 per cent in 1913 and 35.8 in 1901. There has therefore been a shifting of the age distribution of decedents in recent years, in the direction of the older age-groups, beginning with the 10-20 group.

PRAGUE

(From Our Regular Correspondent)

March 1, 1926.

Veneral Disease Census

The first period of reporting of cases of venereal disease occurred in February, 1921. At that time notification was not obligatory. The new law on venereal disease control, enacted July 11, 1922, includes a clause leaving it to the discretion of the ministry of health to require, when necessary, from physicians and medical institutions, notification of venereal diseases. The names of patients are not required to be given. The ministry of health plans to order such reporting over a period of one month every five years. The month of February was selected, and February, 1926, was chosen for the second period of reporting. During the first venereal disease census all the cases under treatment were reportable, but this time reports were confined to cases which came under treatment by physicians for the first time in the course of the month. The reason for this is that the health service is not so much interested in the number of infected persons as it is in the incidence of new infections. The revelation of a big reduction in the incidence of these diseases is anticipated. The total reported this time is over 21,000. By another scheme of notification, venereal patients are compelled to continue treatment until symptomless. Every physician is obliged to report patients by name to the health authorities if they discontinue treatment before they are released by him.

Section for Study and Reform of Health Service

Five years ago a section for the study and reform of health service was organized in the ministry of health in cooperation with the International Health Board of the Rockefeller Foundation. This bureau was composed chiefly of former fellows of the Rockefeller Foundation who were sent to the United States for postgraduate education in public health. To the section an advisory board was added which was supposed to adapt to local needs the new ideas brought forward by the former fellows. Under the auspices of the section, national surveys of tuberculosis and venereal disease have been conducted which served as a basis for national programs to combat these diseases. A bureau for public health education was created in the ministry of health, and public health demonstrations have been organized. Recently the section has been transferred to the state institute of public health, which is being conducted in cooperation with the International Health Board of the Rockefeller Foundation.

New President of Association of Czech Physicians

Prof. Ladislav Syllaba gave his opening lecture, February 8, as the newly elected president of the Association of Czech Physicians in Prague. Professor Syllaba gave a birds'-eye view of the development of this corporation since its foundation in 1862. The association owes its existence to the initiative of J. E. Purkinje, who held the chair of physiology in Prague at that time. The first meetings were held in the lecture room of the physiologic institute, and Purkinje, with his pupils, supplied most of the material for papers and discussions. Purkinje remained at the head of the association until his death in 1869. Since its creation, the association has held meetings every Monday. While most of the lectures come from the different institutes of the medical faculty, practicing physicians show great interest in the proceedings of the association. Thus, the association has become an important instrument for raising the standard of the practicing medical profession. The new president of the Prague Association is the head of the Czech clinic for internal diseases in Prague.

Sickness Insurance

At present, private officials (clerks, accounting officers, supervisors in factories, managers) come under the general sickness insurance law, which includes chiefly industrial and agricultural laborers. The laborers are chiefly interested in the financial benefits from the insurance in case of sickness. On the other hand, private officials are usually employed on contract, and in case of sickness their salaries continue for a certain period. Therefore they are more interested in the quality of the medical service to which they are entitled under the insurance. After long discussion, it has been decided that sickness insurance for laborers shall be separated from that of private officials. In the bill that will be submitted to parliament, the emphasis is laid on medical service. The patient shall be free to choose his physician from a list of practitioners who have declared themselves willing to treat patients under the terms of the insurance fund. This measure, furthermore, satisfies the medical profession, which for a long time has been fighting for this system.

Physical Development of School Children

Recently, in the district of Kralupy, the Czech Anthropological Institute in Prague has weighed and measured 3,000 school children. There is much immigration into this district, owing to intensive industry. Therefore the average child in Kralupy can be taken as representative of the children of an industrial community of Czechoslovakia. The results were tabulated and standards determined for different ages and both sexes. These results were compared with similar figures for 1895. The comparison shows that the children of the present generation are generally one year more advanced in their development than those thirty years ago. The explanation suggests itself that the conditions under which children live have improved. Therefore there may be an earlier development during the preschool age, so that the children enter school in better physical condition than was the case thirty years ago.

Marriages

HERMAN BRYAN, Chufos Province Shantung, China, to Miss Esther J. Love, formerly of Fremont, Ohio, at Shanghai, February 15.

WILMER C. EDWARDS to Miss Lucile B. Postel, both of Richland Center, Wis., February 19.

EDWARD HAROLD MAUER to Miss Anna Felice Egan, both of New Orleans, February 10.

Deaths

George Frederick Keiper ⊕ Lafayette, Ind.; University of Michigan Medical School, Ann Arbor, 1890; fourth vice president, in 1916, member of the House of Delegates of the American Medical Association, 1922, 1923, 1924 and 1925, and a member of the reference committee on amendments to the Constitution and By-Laws, 1924 and 1925; past president and vice president of the Indiana State Medical Association; member of the American Academy of Ophthalmology and Oto-Laryngology, the American Laryngological, Rhinological and Otological Society, the Chicago Ophthalmological Society, Indiana Academy of Ophthalmology and Oto-Laryngology, and the American Bronchoscopic Society; a frequent contributor to medical journals; member of the board of education of Lafayette, 1916-1919; trustee of De Pauw University, 1898-1925; on the staffs of St. Elizabeth's, Wabash Valley and Lafayette Home hospitals, and the Indiana State Soldiers' Home; aged 59; died, March 18.

Robert Edward Lee Newberne ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1893; chief medical supervisor, U. S. Indian Service since 1918; past president of the Philippine Islands Board of Medical Examiners and the Philippine Islands Medical Association; also a dentist; member of the Idaho State Medical Association; formerly lecturer on nervous and mental diseases, legal medicine and medical jurisprudence, University of the Philippines College of Medicine and Surgery, and chief, Free Dispensary Division, Philippine General Hospital; aged 53; died, February 15, at Phoenix, Ariz., of cerebral hemorrhage.

Norman Kerr ⊕ Chicago; McGill University Faculty of Medicine, Montreal, Que., Canada, 1889; member of the Chicago Surgical Society; formerly professor of surgery, Chicago Policlinic and Hospital; on the staff of the Henrotin Memorial Hospital, and at one time on the staffs of the Children's Memorial and Cook County hospitals; served during the World War; aged 58; died, March 8, of heart disease.

Charles Ellery Denison ⊕ New York; Bellevue Hospital Medical College, New York, 1882; for thirty-seven years connected with the board of health; formerly on the staff of the Metropolitan Hospital; aged 68; died, March 3, of epidemic encephalitis contracted about five years ago.

William Archibald Monroe ⊕ Sanford, N. C.; University of Maryland School of Medicine, 1886; past president of the Seaboard Surgical Association; formerly member of the school board, and member of the state legislature; aged 62; died, February 26, of influenza.

Wendell Lee Latimer, Lowndesville, S. C.; Emory University School of Medicine, Atlanta, 1922; physician in charge of the Children's Hospital of the Pennsylvania State Sanatorium, South Mountain, Pa.; aged 31; died, February 19, at Montalto, Pa., of tuberculosis.

George Edgar Robison, Salt Lake City, Utah; College of Physicians and Surgeons, Baltimore, 1898; member of the Utah State Medical Association and the Radiological Society of North America; aged 56; died, February 10.

Lawrence Ingram, Richmond, Va.; Medical College of Virginia, Richmond, 1886; member of the Medical Society of Virginia; formerly president of the Manchester Board of Health; aged 61; died, February 19.

Needham Harvey Grady ⊕ Hot Springs National Park, Ark.; St. Louis College of Physicians and Surgeons, 1901; aged 73; died, February 24, at a hospital in St. Louis, of chronic nephritis and heart disease.

Charles Sebastian Fischer, Hastings-Upon-Hudson, N. Y.; Medical Department of Columbia College, New York, 1881; aged 79; died, January 28, at the Dobbs Ferry Hospital, Dobbs Ferry, of chronic nephritis.

Annie Hays, Clarksville, Ark.; Medical Department of the University of Illinois, Chicago, 1903; member of the Arkansas Medical Society; aged 63; died, February 24, at St. David's Hospital, Austin, Texas.

William Andrew Stevenson, Oil City, La.; University of Louisville School of Medicine, 1907; member of the Louisiana State Medical Society; aged 48; died, February 23, at a sanatorium in Shreveport.

Nimrod Polk Wood ⊕ Independence, Mo.; St. Louis Medical College, 1881; past president of the Jackson County Medical Society; formerly member of the board of education; aged 66; died, February 23.

William A. Fritsch, Evansville, Ind.; Medical College of Ohio, Cincinnati, 1881; Civil War veteran; formerly member of the city and state boards of health; aged 84; died, February 13, of pneumonia.

Stephen Leo O'Brien ⊕ Grand Rapids, Mich.; St. Louis University School of Medicine, 1913; on the staff of St. Mary's Hospital; aged 36; died, February 25, of exhaustion ending in acute psychosis.

Caroline L. Black, New York; New York Medical College and Hospital for Women, New York, 1878; member of the Medical Society of the State of New York; aged 78; died, February 24.

Robert Crichton Molison, Marshalltown, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; member of the Iowa State Medical Society; aged 57; died, February 24.

Charles Dutton, Wakefield, Mass.; Medical School of Harvard University, Boston, 1863; member of the Massachusetts Medical Society; aged 86; died in February, of arteriosclerosis.

Fletcher S. Porter, Pickens, S. C.; College of Physicians and Surgeons, Baltimore, 1893; member of the South Carolina Medical Association; aged 56; died, February 24, of uremia.

John H. Harden, Cheraw, S. C.; University of Maryland School of Medicine, Baltimore, 1887; past president of the Chesterfield County Medical Society; aged 63; died, Dec. 31, 1925.

Charles Travis Trumbo, Seymour, Ind.; Indiana University School of Medicine, Indianapolis, 1922; member of the Indiana State Medical Association; aged 38; died, January 15.

Charles H. Craig, Webb City, Mo.; Missouri Medical College, St. Louis, 1887; formerly county and city physician; aged 68; died, February 19, of pneumonia, following influenza.

Carlton V. Hinman, Bellaire, Mich.; Hahnemann Medical College and Hospital, Chicago, 1882; formerly a druggist; aged 67; died, in February, at a hospital in Traverse City.

Francisco Alvarez Cintron, Jr., Detroit; Chicago College of Medicine and Surgery, 1918; aged 32; died, January 23, at the Grace Hospital, of hemorrhage due to duodenal ulcer.

William J. Hornbarger, Heber Springs, Ark.; University of Arkansas Medical Department, Little Rock, 1884; member of the Arkansas Medical Society; aged 66; died, February 26.

Charles H. Russell, Allegan, Mich.; University of Michigan Medical School, Ann Arbor, 1866; formerly city physician of Hastings; aged 83; died, in January, at Los Angeles.

Martin Goldberger, New York; University of Budapest, Hungary, 1888; aged 62; died, January 29, of cerebral hemorrhage, arteriosclerosis, myocarditis and nephritis.

William R. Cotty, Indianapolis; Eclectic Medical College of Indiana, Indianapolis, 1905; aged 58; died, Dec. 25, 1925, of cirrhosis of the liver and tuberculous enteritis.

Robert Pemberton Gerhart, Linden Hall, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1913; aged 38; died, January 31, of pulmonary tuberculosis.

Thomas Vincent Meacham, New Brunswick, N. J.; Bellevue Hospital Medical College, New York, 1891; aged 55; died, Dec. 27, 1925, of cerebral hemorrhage.

John Arthur Farrell ⊕ Monrovia, Calif.; Albany Medical College, 1910; member of the Medical Society of the State of New York; aged 39; died, February 14.

William Wilson Nelson, Birmingham, Iowa; Jefferson Medical College of Philadelphia, 1860; Civil War veteran; aged 91; died, February 27, of pneumonia.

John S. Beamensderfer, Manheim, Pa.; Jefferson Medical College of Philadelphia, 1883; aged 68; died, February 8, at the Lancaster (Pa.) General Hospital.

Charles Morgan Williams, Washington, N. J.; Jefferson Medical College of Philadelphia, 1897; also a druggist; aged 55; died, February 8, of pneumonia.

Austin D. Searles, Omaha; Medical Department of the Tulane University of Louisiana, New Orleans, 1894; aged 62; was shot and killed, February 18.

Emmet William Sullivan, Cleveland; University of Wooster Medical Department, Cleveland, 1878; aged 70; died, February 8, following a long illness.

William John Kinder, Aldrich, Mo.; University of the South Medical Department, Sewanee, 1897; aged 68; died, at Springfield, February 19.

Edwin Dickens Brantley, Riverton, Wyo.; Vanderbilt University Medical Department, Nashville, Tenn., 1887; aged 57; died in February.

Douglass Henry Smith ⊕ Bath, N. Y.; University of Buffalo Department of Medicine, 1904; aged 46; died, March 4, of heart disease.

Boyce O. Sally, Norway, S. C.; University of Georgia Medical Department, Augusta, 1887; aged 68; died, February 14, following a long illness.

James H. Milam, Dyersburg, Tenn.; Vanderbilt University Medical Department, Nashville, 1883; aged 70; died, in February, of pneumonia.

Daniel Bartholomew Sullivan ⊕ Flint, Mich.; Saginaw Valley (Mich.) Medical College, 1901; aged 50; died, February 18, of uremia.

Charlotte H. Woolley, Brooklyn; New York Medical College and Hospital for Women, New York, 1887; aged 75; died, February 26.

Pennington Kiteley ⊕ Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1922; aged 32; died, October, 1925.

Monroe Anderson, Dallas, Texas; University of Texas Department of Medicine, Galveston, 1888; aged 79; died, January 25.

John W. Whitehead, Bomer, Tenn. (licensed, Tennessee, 1889); for many years served as justice of the peace; died, January 25.

E. F. Conynghame, Underwood, Minn.; Minneapolis College of Physicians and Surgeons, 1886; aged 70; died in February.

Erick Soegaard, Fillmore, Calif.; Medical Department of the University of Illinois, Chicago, 1901; died, Dec. 5, 1925, at Ventura.

William Sanford Bigelow, Philipsburg, Pa.; New York Homeopathic Medical College, 1884; aged 72; died, February 19.

Walter Harris Dinsmore, Vancouver, B. C.; Medical School of Maine, Portland, 1880; aged 68; died, February, at Ottawa, Ont.

Albert Henry Tuttle ⊕ Cambridge, Mass.; Medical School of Harvard University, Boston, 1886; aged 64; died, March 1.

Owen Randolph Altman ⊕ Uniontown, Pa.; Jefferson Medical College of Philadelphia, 1901; aged 54; died, February 23.

Elsie Belle Merritt, Sanitarium, Calif.; American Medical Missionary College, Chicago, 1901; aged 50; died, February 19.

Susan P. Hammond Field, Boston; Boston University School of Medicine, 1880; aged 85; died, in December, 1925.

James E. Hyett, St. Marys, Kan.; Chicago Medical College, 1904; aged 55; died, February 26, at a hospital in Topeka.

John J. O'Brien, Chapman, Kan.; University of Louisville (Ky.) School of Medicine, 1890; aged 60; died, February 12.

Frederick Andrew Hess ⊕ Chicago; Rush Medical College, Chicago, 1873; aged 74; died, Dec. 25, 1925, of angina pectoris.

Homer T. Jackson, Verona, N. Y.; University of Buffalo Department of Medicine, 1881; aged 79; died in February.

Charles Albert McNeill, Indianapolis; Medical College of Indiana, Indianapolis, 1901; aged 50; died, February 19.

William Garrison Mizner, Oakland, Calif.; Cooper Medical College, San Francisco, 1889; aged 61; died in February.

Lewis K. Riley, Richmond, Calif.; Cooper Medical College, San Francisco, 1882; aged 84; died in January.

L. H. Ross, Ekin, Ind. (licensed, Indiana, 1897); aged 72; died, January 13, of cerebral hemorrhage.

Charles F. Howell, Riverside, Calif.; Keokuk Medical College, 1901; aged 59; died, Dec. 27, 1925.

John Bledsoe, Perry, Mo.; Missouri Medical College, St. Louis, 1867; aged 86; died, Dec. 27, 1925.

J. R. Echols, Lubbock, Texas (licensed, Texas, under the Act of 1907); died, February 8.

Correspondence

ELECTROLYSIS FOR SUPERFLUOUS HAIR

To the Editor:—May I add some comments to the inquiry appearing in The Journal, March 6, page 709, as to the proper outfit for the removal of superfluous hair by electrolysis, and the reply thereto, which does not quite cover two important points.

Electrolysis is based on the polarity action of the constant (galvanic) current. A fine, bulbous pointed platinum needle is inserted into the hair follicle, and connected to the negative pole (cathode) of a source of galvanic current: either a few dry cells connected into a battery, or the commercial "direct" current passing through a suitable resistance (rheostat) or the "alternating" current changed into a direct one by a motor generator. A gauze or sponge covered "indifferent" electrode, held by the patient, is connected to the positive pole (anode). A current of about 2 milliamperes, flowing for not more than twenty seconds, will produce sufficient caustic sodium hydroxide around the needle to destroy the lining of the hair follicle; at the same time hydrogen is liberated, which appears at the mouth of the follicle with a slight crackling noise.

It is perfectly evident why the instrument described by the inquirer produced nothing but a painful sensation: because it was a simple faradic coil, totally unsuited for what it was bought for. An induced (faradic) current, flowing with unequal alternation from one pole to the other, lasting only about 1⁄1000 second in either direction, is totally devoid of polarity action, but will produce a painful sensory stimulation. Such a current cannot be measured by any milliammeter.

As long as physicians will depend on the advice of salesmen for the selection and proper use of their electrotherapeutic apparatus, they and their patients will have to expect some very disappointing results.

Richard Kovacs, M.D., New York.

INSULIN IN EXCESSIVE VOMITING AND ECLAMPSIA

To the Editor:—The editorial comment in The Journal, February 20, entitled "Insulin in Excessive Vomiting and in Eclampsia" was of distinct interest to me. I am firmly convinced of the infinite possibilities for harm which exist in the advice that insulin be given to these patients. This is particularly true of the recommendations of Stander and Duncan, and while I believe that insulin should not be added to the glucose injections given for the vomiting of pregnancy, it seems to be positively dangerous in eclampsia.

Shortly after hearing my paper on "Hyperemesis Gravidarum," which was read at the last session of the American Medical Association at Atlantic City, Thalhimer wrote to me asking me to withhold its publication because he was certain that I was wrong in my advice against the addition of insulin to the glucose, and that he was right. I suggested that we let the Toronto group referee the matter, and sent all his reprints together with mine to Professor Macleod. He was away, but one of his assistants replied by saying that the opinion of the entire group was represented by an article to which he gave me the reference. This was in *Medicine* (3: 284 [Aug.] 1924) by W. R. Campbell and J. J. R. Macleod, and read as follows:

> The use of insulin in pernicious vomiting of pregnancy is, in our opinion, unnecessary. No case of postoperative acidosis has required it and it is difficult to see what purpose it could serve. Its use in nonketonic acidoses is even more questionable, and indeed one may be permitted to doubt its value in conditions other than those in which there is a distinct deficiency of endogenous insulin production. Those who insist on regarding all the ills the flesh is heir to as due to an indefinite endocrine

unbalance will do well to pause before applying insulin recklessly. Insulin is a powerful drug.

Thalhimer suggested the use of insulin in addition to glucose to control the condition [referring to Thalhimer's work in vomiting of pregnancy] in severe cases. It is difficult to appreciate the use of the drug in this type of case. In Toronto no case of uncomplicated pernicious vomiting sufficiently severe to warrant the trial of insulin in addition to fluids and glucose has been encountered in the last two years [referring here to the statement that "most of these cases can be controlled satisfactorily by administering glucose and an adequate amount of fluids"].

This article was sufficiently corroborative of my own opinions, so that I had no hesitancy about proceeding with the publication of my paper, and wrote Thalhimer accordingly. In fact, if I had known of this statement by these authorities in time to include it, additional force would thus have been given to my arguments.

Thalhimer's idea is so plausible, that because insulin with glucose is useful in diabetic acidosis so should it also be more valuable than glucose alone in similar conditions of nondiabetic origin, that it is being generally accepted without question. As a matter of fact, the theory of the treatment of the two states is fundamentally different in each instance. In the one, insulin is given on account of the diabetic lack of endogenous insulin with glucose to buffer it or protect the patient against the ill effects of insulin overdosage, whereas in toxemic acidosis of pregnancy the glucose is given for its liver-sparing effect and to restore the depleted liver, storage rather than combustion being the desired effect. This patient presumably has her usual endogenous insulin production unimpaired.

I think that Thalhimer's conclusions have been based on too few cases, and I have been unable to disregard the opinions on the action of insulin held by such authorities as Macleod and Campbell, especially when my own clinical experience coincides with this. Incidentally, Harding has just published (*Am. J. Obst. & Gynec.*, January) a similar conclusion; and, while he neglects, as has been the case more than once before, to refer to my published opinions on this, making no reference whatever to my last article, he agrees nevertheless that insulin should not be used.

I have been unable to detect any advantage from the addition of insulin to glucose in these cases; but, admitting that this does exist, it must still be granted that glucose alone is safe and effective, whereas, to quote the very fathers of insulin, "it is an exceedingly dangerous drug." It does not seem possible that a theoretical advantage which is slight clinically, if it even exists at all, offsets the distinct risk of this drug in nondiabetic acidosis. My definite opinion is that Thalhimer's reasoning is incorrect and that the addition of insulin is actually contraindicated. As I stated in my last article, if a hyperglycemia still persists after the administration of insulin, there is as much if not more reason for feeling that any beneficial effects of the treatment are due to the persisting excess of sugar over normal, as to the presence of some insulin, especially when it has been shown that glucose buffers and invalidates the action of insulin in a definite and constant ratio.

Thalhimer's chief argument in favor of insulin with glucose, as I understand it, is that the acidosis of these cases, as evidenced by acetone and diacetic acid in the urine, disappears more quickly by his method than by mine. If there is any difference, it is only a matter of a few hours at the best.

In the meantime, the note of warning which I tried to sound is being utterly ignored. Stander and Duncan of Baltimore report, as you point out, only six cases of eclampsia, with recovery in all (the last thirteen I have had recovered likewise, eight of them without insulin, but this proves nothing) and if they continue their tests they will find many eclamptic patients with low blood sugar (as in the table in my article on "Intravenous Injections of Glucose in Toxemia of Pregnancy" The Journal, Jan. 14, 1922, p. 92).

This much is a conceded fact in eclampsia: There is a tremendous expenditure of muscular energy during each convulsion, so that the patient may be compared to a man who has just run a strenuous race. In his case it is obvious that insulin should not be administered, because under the circumstances the risk to him would be far greater than if he had been eating and resting. Nor does he need insulin to help him "metabolize" the food or, better still, the sugar that should be given him after his race, because his endogenous insulin production is normal. Is it logical reasoning to treat what is nothing more than a variable symptom, so far as we know (hyperglycemia in eclampsia), by giving insulin when we do know that under comparable circumstances it is harmful and dangerous?

There are, it seems to me, boundless possibilities for harm in the recent publication of Stander and Duncan, as well as the general recommendation that insulin be used with glucose in all of these toxemias of pregnancy. Even Thalhimer agrees that it is still an unsettled question, and until it is settled there is an interval in which different workers are bound to be affected differently. Many will take it as settled and will push the use of insulin. Stander and Duncan were undoubtedly inspired by Thalhimer's work, and the line of reasoning which will follow on the part of innumerable physicians throughout the country will be, "If at Hopkins they believe that insulin is good for eclampsia, we will use it. If the patient does not improve promptly, we will give more, and more, and more until something happens."

Until the action of insulin is definitely understood and no longer a highly theoretical subject, the dangers and uncertainties of the drug should be pointed out in any discussion of its possible effect in pregnancy toxemias, or in other nondiabetic acidoses. Paul Titus, M.D., Pittsburgh.

VITAMIN POTENCY OF COD LIVER OIL

To the Editor:—I was interested in the query on the emulsification of cod liver oil and vitamins (The Journal, February 27, p. 645), and do not believe that general opinion agrees with your statements that emulsified cod liver oil is equal in vitamin potency to the unemulsified cod liver oil. This would hardly seem true if for no other reason than that emulsified oil contains not more than 50 per cent of cod liver oil and consequently there would be 50 per cent less vitamin in the same dose. Tests made on a number of samples of emulsified cod liver oil have shown that even when allowance is made for the difference in cod liver oil content, there is proportionately less vitamin A content in emulsified cod liver oil. This may be due to the fact that vitamin A in emulsified oil is less stable than in oils not emulsified. The antirachitic factor, or vitamin D, is apparently not as much affected in emulsion as is vitamin A.

John F. Anderson, M.D., New Brunswick, N. J.

"TRACHOMA AMONG THE NORTH AMERICAN INDIANS"

To the Editor:—In The Journal, February 6, appears my paper on this subject, followed by an elaborate discussion, the latter carrying the inference that the program outlined by the Department of the Interior through its Indian Bureau did not admit of practical application. The reports of the bureau since those remarks were made have shown accomplishments decidedly in advance of what were anticipated, and I take this opportunity to ask that you give publicity to the additional facts supplied to me by Assistant Commissioner Merritt. In the declining days of 1925, he informed me that in 1925 some 68,223 Indians were examined for trachoma, of whom 14,036 were found to have the disease. There were performed 8,455 operations, and 5,581 cases were treated otherwise. This represents only the trachoma work of the special physicians detailed for this purpose. All the Indian Bureau's physicians took part in the program, but their reports are not as yet available. Our contention that the Indian Bureau was the proper source from which to attack this problem seems to be justified by their results. The assumption that it is a problem belonging to the adjacent white communities is an acknowledgment of helplessness. The great bulk of cases that may be approached through the bureau points the way to the solution of the problem.

The need of hospitals well equipped with nurses must not be overlooked. L. Webster Fox, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CURAY LIGHT APPLICATORS

To the Editor:—Will you kindly give me information about the Curay light applicator, which is claimed to supply a great amount of therapeutically active ultraviolet rays? Kindly omit name.

M.D., Connecticut.

To the Editor:—What is the accepted value of ultraviolet ray therapy in otolaryngology? The manufacturers of equipment are claiming a great deal, but I see very little in the literature by recognized leaders in the specialty. What is the status of the Curay light? Please use initials only.

R. W., Virginia.

To the Editor:—Kindly give your opinion on the effectiveness of a new instrument supposed to generate the ultraviolet ray. This instrument is made and sold by the Curay Company, 383 Boylston Street, Boston. How does it compare with Hanovia's alpine sun lamp?

E. G. LaRiviere, M.D., New Bedford, Mass.

Answer.—The source of light in a Curay lamp is an incandescent tungsten filament enclosed in a glass bulb. It is, as a matter of fact, an ordinary automobile headlight lamp. When used in the Curay apparatus, the lamp is operated on a higher current than its normal rating carries. The filament is therefore heated to a higher temperature than it is when used on an automobile. Accordingly, the average length of life of the lamp is greatly reduced.

The spectral energy distribution of the Curay lamp is that of a hot body radiator, and it is possible by means of Planck's equation to calculate the relative amount of emitted energy for any spectral region. It is well known that a radiator of this type emits most of its energy in the form of heat, but a small fraction of energy will be emitted as ultraviolet energy. Since the temperature of the filament is much below the temperature of the sun, the radiant energy which it emits will contain a smaller proportion of ultraviolet than the energy of sunlight.

Comparing the Curay lamp with the quartz mercury vapor arc lamp, the amount of ultraviolet rays emitted is insignificant. Planck's equation does not apply to the spectral energy distribution of the mercury vapor arc. The mercury vapor arc emits a relatively large fraction of its energy in the ultraviolet region of the spectrum.

It follows that the light emitted by the Curay lamp is not comparable with sunlight, for not only is the total amount of energy emitted less than that of sunlight, but a much smaller proportion of the energy emitted is in the form of ultraviolet rays.

Further, the Curay lamp has a glass bulb, which will strongly absorb the ultraviolet rays given off by the filament. The Curay Company supplies a photograph of a spectrum stated to be that of the Curay lamp. This photograph shows a spectrum extending as far as the ultraviolet—or perhaps farther—and then a spectrum of sunlight alleged to have been made by the same spectroscope and under similar conditions. The photograph gives no information as to the comparative intensities of the light in the ultraviolet region.

An exposure of the skin in actual contact with the quartz rod "applicator" supplied with the Curay lamp for one-half hour showed no ultraviolet erythema. An exposure of three and one-half minutes at a distance of 1 meter with a quartz mercury vapor lamp produced a marked erythema.

The Curay Company also supplies letters containing accounts of supposed "cures" of colds and bacterial infections, but these concern uncontrolled experiments. There seems to be no actual evidence that the lamp was a contributing factor in the "cure."

"COPPER ITCH"

To the Editor:—In a local copper works, several of the men who are employed there are suffering with a form of dermatitis which they call "copper itch." This form of dermatosis affects the arms and legs and is in the form of an itching, red and somewhat scaly eruption. The lesions tend to become chronic, with thickening of the epiderm and lichenification. Kindly report to me the most efficient form of therapy for these lesions; if you mention formulas, please give percentages and vehicles employed.

Elmer G. Shelley, M.D., North East, Pa.

Answer.—According to Kobert (Lehrbuch der Intoxikationen, Stuttgart, 1897) workers in copper may develop a greenish coloration of the skin, conjunctiva and hair and a red purpuric line on the gums. Winkler (Die Schädigungen der Haut durch Beruf und gewerbliche Arbeit, Leipzig **2**, nos. 1-4, 1925) has observed similar changes in ammunition workers and watch makers. In the latter, beneath the finger nails, he has sometimes found greenish deposits containing copper. Ravogli has described two cases of dermatitis occurring in workers in a brass foundry. In both these cases the skin of the legs was red and edematous, whereas that of the thighs was covered with an intensive pruritic papular eczema. After involution of the lesions there remained a dark brown pigmentation. In addition to these changes there were necrotic ulcers on the thighs in one of the cases. Teleky-Brezina (Internationale Uebersicht über Gewerbekrankheiten, 1921) saw a series of cases in girl metal workers who had developed a dermatitis on the finger tips from soldering brass objects. Herxheimer (*Dermat. Wchnschr.*, 1912, no. 1) described cases of dermatitis developing as a result of the action of weak sulphuric acid and oil on copper wire. Electrical workers sometimes become tattooed from contact with copper and brass.

The treatment should first of all consist in protecting the affected workers from contact with the copper. As the legs and arms are chiefly affected, it would be well to attempt by means of long sleeves and boots or puttees to protect the extremities from the copper dust. Thick denim overalls with sleeves bound tightly at the wrists and the trouser legs at the shoe tops might be of service if washed daily or several times weekly.

In the early acute stage one of the calamine lotions might be useful. Sometime later a simple soothing protective salve might be applied twice daily after cleansing of the parts with olive oil. In the old cases, radiotherapy consisting of ¼ or ½ skin unit doses every ten days to two weeks for three or four doses would probably be found very effective.

VARIATIONS IN WASSERMANN REACTION

To the Editor:—I am frequently receiving, on cases, Wassermann reports that vary greatly in two-day intervals and the cases are not receiving treatment. Examples of the variation are shown below:

Name	1/17/26	1/19/26	1/22/26	1/24/26
A. B..........	4 plus	2 plus	Negative	2 plus
A. G..........	4 plus	Negative	Plus-minus	Negative
A. S..........	1 plus	2 plus	4 plus	2 plus
R. S..........	4 plus	Negative	4 plus	

The laboratory informs me that this may be caused by the daily change in the blood of the patient or may be due to the minute dilutions of the various agents that enter into the Wassermann reaction. As these patients were not receiving any treatment during this time and, as far as I know, had never received any treatment, I do not consider this explanation satisfactory. These Wassermann tests are made as part of a routine examination, and when such a marked difference is noted in such a short interval, no treatment being given, it causes me to question the value of these reports. Would you be kind enough to advise me if this is a frequent occurrence in the Wassermann report? Also, your comments and any suggestions would be appreciated. Please omit my name and address.

M.D., New York.

Answer.—Such widespread discrepancies in Wassermann reports on apparently normal patients are not of frequent occurrence when the Wassermann test is properly performed. Formerly Craig cited such variations, but his work has not been substantiated by the majority of serologists.

Assuming that glassware is carefully cleaned, that uniform type and period of incubation is employed and that the same antigens and the same amboceptor are used from day to day, an explanation for such phenomena may be given under the following heads:

1. The complement obtained from guinea-pig serums varies in activity and its ability to be bound by syphilitic reagin. For that reason, pooled serum from at least three guinea-pigs aids in giving a more uniform product. The blood should be taken from pigs that have had no food the day of bleeding.

2. The older form of titrating complement gave too wide a variation between two units of one day and two units of the next.

Example: Originally 1:10 dilution of complement was used with 0.1 cc. intervals; today, 1:30 dilution of complement is used with 0.05 cc. intervals, therefore greatly refining the sensitivity of the test.

3. The amount of native amboceptor present in the patient's serum may vary somewhat at different intervals, making a factor in variation of the test when it is not absorbed as routine practice. This may show more particularly when shorter periods of incubation are used rather than in the case of the eighteen hour icebox fixation.

THE KROMAYER LAMP

To the Editor:—Please advise me regarding the efficiency, therapeutic dependability and ethics in the use of the Kromayer lamp, put out by *the Hanovia Chemical and Manufacturing Company, Newark, N. J.* Will these lamps do what is claimed for them therapeutically?

C. B. Greear, M.D., Honaker, Va.

Answer.—According to determinations made by the Hanovia Manufacturing Company and which correspond to those of the Bureau of Standards, the Kromayer lamp emits no radiation shorter than 2,000 angström units or longer than 14,000 angström units. Of the total radiation emitted, approximately 65 per cent falls in the ultraviolet field, and since the input of energy is 5 amperes, with a 70 volt drop across the burner, and since the radiation is confined to a small area, this lamp supplies as great intensity of ultraviolet per unit area as any commercial source designed for therapeutic use. The apparatus is dependable both mechanically and therapeutically.

Concerning the question, "Will these lamps do what is claimed for them therapeutically?" The Kromayer lamp does produce the ultraviolet rays, but no assertion can be made as to the therapeutic properties of the rays. The company has collected the reports of results of investigations with the lamp, and supplies the references.

GONOLIN—LUESAN

To the Editor:—I am enclosing a leaflet that I would like to ask you about. The product described is recommended by one of the oldest physicians' supply houses, and I have bought drugs of them, with perfect satisfaction, for years. It would seem that they would hesitate to sell something of doubtful value on account of their reputation, but I have not seen anything about this in the literature. Has it been passed by the Council?

L. C. Knight, M.D., Carthage, Ill.

Answer.—The leaflet sent deals with Gonolin and Luesan, neither of which has been passed by the Council. The two products are manufactured by the Horovitz Biochemic Laboratories Company, 67 Fulton Street, New York. A. S. Horovitz, president of the Horovitz Biochemic Laboratories Company, was referred to in connection with the asserted cancer cure "Autolysin" (The Journal, July 24, 1915, p. 336). Later he appears to have been largely responsible for the "Proteogens" which the Council on Pharmacy and Chemistry declared inadmissible to New and Nonofficial Remedies (Proteogens of the William S. Merrell Company, The Journal, July 12, 1918, p. 128). Subsequently the company, of which A. S. Horovitz is president, prepared a line of "Protein Substances" similar to the "Proteogens," each one being claimed to be more or less specific against a given disease or condition. The claims advanced for Gonolin and Luesan bear a striking similarity to those made for the discredited "Proteogens."

No product of the Harvey Company, the firm named as distributor on the circular sent by our correspondent, has been reported on by the Council on Pharmacy and Chemistry or by the A. M. A. Chemical Laboratory. However, this is one of the firms some of whose tablets were found deficient by the Connecticut Agricultural Experiment Station (Dependability of Dosage in Tablets, The Journal, July 27, 1918, p. 300; Nov. 2, 1918, p. 1520). In a subsequent report (March, 1925) of the Connecticut Agricultural Experiment Station, tablets of the Harvey Company were again reported as having undue variation in content.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

Arkansas: Little Rock, May 11-12. Sec., Dr. J. W. Walker, Fayetteville. Homeo. Board, Little Rock, May 11. Sec., Dr. A. A. Pringle, Eureka Springs. Eclectic Board, Little Rock, May 11. Sec., Dr. Claude E. Laws, Fort Smith.

Colorado: Denver, April 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

District of Columbia: April 13. Sec., Dr. Edgar P. Copeland, 1801 Eye St., Washington, D. C.

Idaho: Boise, April 6. Commissioner of Law Enforcement, F. A. Jeter, Boise.

Illinois: Chicago, April 6-8. Supt. Regis., Mr. V. C. Michels, Springfield.

Minnesota: Minneapolis, April 6-8. Pres., Dr. Thomas Lowe, Pipestone.

Montana: Helena, April 6-8. Sec., Dr. S. A. Cooney, Helena.

National Board of Medical Examiners: Part I, June 21-23; Part II, June 22-23. All applications should be made on or before May 15. Sec., Dr. J. S. Rodman, 1600 Walnut Street, Philadelphia.

Nevada: Carson City, May 3. Sec., Dr. Simon L. Lee, Carson City.

New Mexico: Santa Fe, April 12-13. Sec., Dr. W. T. Joyner, Roswell.

Rhode Island: Providence, April 1-2. Sec., Dr. Byrum U. Richards, Providence.

Texas: Dallas, American Board of Otolaryngology, April 19. Sec., *Dr. W. H. Loeb, 1402 South Grand Blvd., St. Louis, Mo.*

Utah: Salt Lake City, April 6. Director, Mr. J. T. Hammond, Salt Lake City.

Ohio January Reciprocity Report

Dr. Henry M. Platter, secretary of the Ohio State Medical Board, reports that 29 candidates were licensed at the reciprocity meeting held at Columbus, Jan. 5, 1926. The following colleges were represented:

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Alabama School of Medicine	(1909)	Alabama
Denver and Gross College of Medicine	(1908)	Colorado
University of Colorado School of Medicine	(1910)	Colorado
George Washington University Medical School	(1925)	Dist. Colum.
Howard University School of Medicine	(1924, 2)	Dist. Colum. Maryland
Rush Medical College	(1924)	Illinois
Indiana University School of Medicine	(1918) (1924)	Indiana Illinois
State University of Iowa College of	[illegible]	Iowa
University of Louisville School of		Kentucky
Johns Hopkins University Medical	 (1921)	Virginia Maryland
University of Maryland School of Medicine	(1924)	Maryland
Creighton Medical College	(1922), 1924)	Nebraska
Columbia University College of Phys. & Surgs.	(1920)	New York
Jefferson Medical College of	[illegible]	Penna.
Temple University Department		Penna.
University of Pennsylvania Sc		New York
Meharry Medical College	(1916) Louisiana, (1922) Tennessee, (1924)	Kansas
Vanderbilt University School of Medicine	(1900)	California
University of Vermont College	[illegible]	Vermont
University of Virginia School		Virginia
Queen's University Faculty of		New York
University of Toronto Faculty of Medicine	(1904)	Penna.
University of Vienna, Austria	(1899)	*W.Virginia

* Verification of graduation not completed by the American Medical Association.

Alabama January Examination

Dr. Samuel W. Welch, chairman of the Alabama Board of Medical Examiners, reports the written examination held at Montgomery, Jan. 12, 1926. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Eleven candidates were examined, all of whom passed. Four were licensed by reciprocity and 1 by endorsement of his credentials. The following colleges were represented:

College PASSED	Year Grad.	Number Passed
Emory University School of Medicine	(1925)	2
Rush Medical College	(1925)	1
Tulane University of Louisiana School of Medicine	(1925)	1
University of Maryland School of Medicine	(1925)	1
Medical College of the State of South Carolina	(1925)	1
Meharry Medical College	[illegible]	1
University of Tenn		1
Dalhousie Universi		1
University of Toro		2

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine	(1922)	Georgia
University of Louisville School of Medicine	(1921)	Kentucky
Jefferson Medical College	[illegible]	Penna.
Memphis Hospital Medic		Mississippi
University of Tennessee		Tennessee

College ENDORSEMENT OF CREDENTIALS	Year Grad.	Endorsement with
Rush Medical College	(1920)	N. B. M. Ex.

Book Notices

THE PRINCIPLES AND PRACTICE OF ENDOCRINE MEDICINE. By William Nathanial Berkeley, Ph.D., M.D., Recently Attending Physician at the Good Samaritan Dispensary, New York. Cloth. Price, $4.50. Pp. 368, with 60 illustrations. Philadelphia: Lea & Febiger, 1926.

The author of this volume on the glands of internal secretion has good acquaintance with the scientific facts, and, in most instances, presents them fairly and critically. Less critical discrimination is shown in the fields in which in earlier years he had personal contact with experimental work. The chapters on the thyroids, the suprarenals and the sex glands seem best. That on the pineal body is out of proportion in length to what is known concerning the rôle of this body in health and disease. Moreover, the author promotes the use of pineal extract, given by mouth to "backward" children for a long time to improve their mentality. The author seems unacquainted with the numerous reliable researches that show no direct influence of sympathetic nerves on the tonus of skeletal muscles (pp. 30, 31, 143). He states that thyroidectomy in rabbits is without effect (p. 42). This is contrary to fact. "Marine's statement that the immediate cause of goiter (simple) is lack of iodine can hardly be affirmed any more than it can be claimed that the immediate cause of malaria is lack of quinine" (p. 63).

Speaking of his own parathyroid preparation administered by mouth, he reports "remarkable benefits" in the majority of cases of paralysis agitans, despite the improbability of parathyroid origin of this malady, and the indication that the parathyroid hormone is ineffective by the oral route. Showing good judgment in other matters, when it comes to his own parathyroid preparation he accepts support by the ordinary testimonial route:

> The wife of another recent patient writes, we are greatly encouraged and hope he will be entirely well.

Again he says:

> Primary anterior lobe deficiencies of a "functional" or, at least, temporary and curable character, in boys and girls of the infantile type . . . a long series of New York public school children of this character have passed through my hands . . . in the last fifteen years. They receive whole pituitary (special formula prepared for me by a New York wholesaler) in suitable doses, and in the course of one or two years they grow remarkably (p. 188).

We have the right to ask how much the *control* group of similarly "temporary" infantile children grew in the same length of time.

> In the treatment of Froelich's disease the prolonged administration of whole pituitary gland preparation is the most rational procedure (p. 195).

This, despite the evidence of Evans, Smith and others that anterior lobe hormone is ineffective by the oral route.

On page 261 he states that he still "with satisfaction" uses in diabetes his own extract of the pancreas given by mouth, despite the evidence that insulin, except in enormous quantities, is ineffective by that route.

> Ligation or partial excision of the vas deferens causes a slow atrophy of the seminiferous cells (p. 271).

This has been disproved by Moore and others.

> A high degree of sexual ardor at the time of intercourse probably modifies favorably the growth if not the structure of the fertilized ovum (p. 295).

The evidence for this is cited from King Lear.

The author recommends pluriglandular therapies:

> In all cases of depressed metabolism, retarded sex development, and diminished growth, thyroid and anterior pituitary, and probably pineal will act synergically (p. 344).
>
> In frank cretinism it has seemed to me useful to supplement the action of the thyroid with whole pituitary, pineal, and the proper gonad. When the patient is carefully watched, pluriglandular therapy can at least do no harm (p. 345).

The last statement is probably true in regard to the patient's body, but what about the patient's pocketbook and the doctor's mind?

The same kind of therapy is recommended in so-called endocrine obesity:

> It may even be well to give thyroid, pituitary and ovarian (or testis) extract in one pill. . . . The food supply should be slowly diminished and this medication slowly increased until the patient loses 1.5 to 2 per cent of his body weight per month (p. 356).

Why reduce the food supply if obesity is of endocrine origin and curable by feeding endocrine mixtures? By speeding up metabolism, increasing nervous tension, and increasing the energy expenditure in muscular work, thyroid extract will by itself reduce body weight in obesity, even on a uniform intake of food.

The book is written from the standpoint of the clinical practitioner for physicians in active practice. But, curiously enough, the author shows greater erudition, critical judgment and common sense in the presentation of the experimental data than in the presentation of the clinical data. The volume is therefore a "mixed blessing" in this era of mushroom growths of monographic endocrinology.

PRAKTIKUM DER CHIRURGIE. Von Prof. Dr. O. Nordmann, Dirigierender Arzt am Auguste-Viktoria-Krankenhaus Berlin-Schöneberg. Third edition. Paper. Price, 33 marks. Pp. 796, with 511 illustrations. Berlin: Urban & Schwarzenberg, 1925.

In this edition, Nordmann's Praktikum of Surgery has been considerably altered and enlarged, bringing the material to date. The scheme remains essentially as before. The work is the outgrowth of a series of articles contributed to the *Medizinische Klinik* dealing with practical points in general and special surgery, and is designed to bridge the gap between the theoretical knowledge learned in medical school and the problems of actual practice. It is also designed to be of assistance to practitioners who do no active surgery, so that they may more readily understand surgical operations. The book begins with a general survey of operative procedure, including preparation of the operating room and instruments; patient and operator; anesthesia, general, regional and local; treatment of wounds and the after-care of wounds; postoperative complications; pyogenic infections of the various tissues; septic infection; osteomyelitis; chronic surgical infectious diseases; important disturbances of nutrition and enervation; diabetes in surgery; diagnosis and treatment of neoplasms; surgical diseases of the tendons, nerves and muscles; surgical diseases of joints and bones, and indications and technic of amputations, including a discussion of prostheses. The latter half of the book deals with special surgery, discussing the surgical diseases and operations regionally. The author states in his preface that he has not attempted to write a textbook but that he hopes to stimulate reference to textbooks. The field he attempts to cover is so large that of necessity the material is general and would be of no especial value except to a practitioner of limited training. In this country, where the first-class medical schools require, as a prerequisite to obtaining a degree, a hospital internship of at least one year in one of the larger hospitals, such a book has little place.

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS. By R. C. Wingfield, M.B., M.R.C.P., Medical Superintendent, Brompton Hospital Sanatorium. Cloth. Price, $3. Pp. 134, with 27 illustrations. New York: Paul B. Hoeber, Inc., 1925.

The preface states that this little volume is primarily intended for medical students and men in the general practice of medicine. Keeping in mind, therefore, that this book was not intended for the specialist but for the man in general practice eager to learn what the specialist believes and teaches, we approach the book wholly from that angle. Certain statements are detrimental to the best interests of the general practitioner. In discussing the subject of tubercle bacilli in sputum, the author states that the administration of potassium iodide for a week will often produce sputum. This method is decried by most men simply because of the deleterious effect on the lung produced by the administration of potassium iodide. Men in practice in America will not agree with the statement that failure to find disease by physical examination justifies complete reliance on roentgen-ray technic. This statement is reiterated later in the book and gives the physician in pursuit of knowledge the impression that it is more or less a fallacy to learn physical diagnosis when diagnosis can so easily be made with the aid of the roentgen-ray machine. Treatment of tuberculosis by the somewhat antiquated method of the administration of potassium iodide and chlorine water is again revived. What has been said before relative to the administration of iodide for diagnosis cannot be too strongly emphasized when this method is advised for treatment. The chapters on pneumothorax and thoracoplasty are rather incomplete and leave much to the imagination. There are many things in the book that are commendable. The advice relative to sanatorium treatment, treatment with tuberculin, and many pages of roentgenograms help to improve the book. Yet one cannot but feel that this small volume on tuberculosis is just another book on a subject that has been well covered in the past; that it has added nothing new to our knowledge, and that it is not presented in a better way than in many other books now available.

Troubles de la fonction gastrique et syndromes associés chez les tuberculeux pulmonaires. Par le Docteur Pierre Marsal de la Faculté de médecine de Nancy. Travail de la clinique de M. le Professeur agrégé J. Parisot. Paper. Pp. 315, with illustrations. Paris: A. Maloine, 1925.

Dr. Marsal has made a careful study of gastric disturbances as they appear in the course of pulmonary tuberculosis. He presents an extensive review of the literature on the subject, which is enlightening in that it directs attention to the gropings of medical men in this field a few decades ago. The present work is based on observations made in sixty-five cases of gastric trouble complicating pulmonary tuberculosis. Marsal properly disapproves of forced feeding in the treatment of tuberculosis and, from the energy of his remarks, it would appear that the French physician is still prescribing a rich diet. The author quotes Daremberg, who said that the stomach is the laboratory of health for the consumptive. Marsal also says, "The better the stomach, the better the prognosis." Considerable space is given to radioscopic examination of the stomach; errors in motility and "deformities" are discussed, and methods of arriving at results are compared. The author concludes, on this point, that there is no more a radiologic tuberculous stomach than there is a clinical tuberculous stomach. The results of observations on deformity, motility, hypertonicity and spasms of the stomach are presented. Other subjects considered are the chemistry of the gastric secretions, the pathologic anatomy and the "emetic cough" so well known to those who treat the tuberculous. After a study of emetic cough, the author concludes that the best results are obtained by limitation of diet. Medicinal treatment is best effected by the use of belladonna or its alkaloids and full doses of bismuth subnitrate. The work represents a careful study of a subject not always sufficiently considered by physicians.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

The Principles and Practice of Medicine. Designed for the use of practitioners and students of medicine. Originally written by the late Sir William Osler, Bt., M.D., F.R.S. Revised by Thomas McCrae, M.D., Fellow of the Royal College of Physicians, London. Tenth edition. Cloth. Price, $7.50. Pp. 1233, with illustrations. New York: D. Appleton & Co., 1926.

The most recent edition of a medical classic, the new editor having retained everything possible from previous editions, except so far as new knowledge required elimination.

Lead Poisoning. By Joseph C. Aub, Lawrence T. Fairhall, A. S. Minot, and Paul Reznikoff. With a chapter on the prevalence of industrial lead poisoning in the United States. By Alice Hamilton, from the Department of Physiology, Harvard School of Public Health, and the Medical Clinic, Massachusetts General Hospital. Cloth. Price, $4. Pp. 265, with illustrations. Baltimore: Williams & Wilkins Company, 1926.

Excellent monograph on a most widespread industrial disease.

Krankheiten und Hygiene der warmen Länder. Ein Leitfaden für die Praxis. Von Prof. Dr. Reinhold Ruge, Marine-Obergeneralarzt A.D. in Klotzsche bei Dresden; Prof. Dr. Peter Mühlens, Marine-Generalarzt A.D. und Abteilungs Vorsteher am Tropeninstitut in Hamburg, und Prof. Dr. Max Zur Verth, Marine-Generoberarzt A.D. und Oberregierungs-Medizinalrat in Hamburg. Second edition. Paper. Pp. 491, with 457 illustrations. Leipsic: Dr. Werner Klinkhardt, 1925.

Remarkably fine presentation of views of Hamburg school of tropical medicine.

Non-Surgical Treatment of Diseases of the Mouth, Throat, Nose, Ear and Eye. By Thomas H. Odeneal, M.D., Otologist, Rhinologist, Laryngologist and Ophthalmologist to the Beverly Hospital Corporation, Beverly, Massachusetts. Cloth. Price, $4 net. Pp. 428, with 4 illustrations. Philadelphia: P. Blakiston's Son & Co., 1926.

A book planned for general practitioners but rather uncritical in matters of therapy.

Historical, Legal, and Statistical Review of Eugenical Sterilization in the United States. Eugenical Sterilization: 1926. By Harry H. Laughlin, Eugenics Record Office, Cold Spring Harbor, Long Island, New York. Paper. Pp. 75. New Haven: American Eugenics Society, 1926.

Valuable compilation indicating trend of this type of preventive legislation.

Pancréatites chroniques avec ictère. Causes, diagnostic et traitement). Valeur et résultats eloignés de la cholécystogastrostomie. Par le Dr. Pierre Mallet-Guy, Interne lauréat des hôpitaux de Lyon. Préface de M. le Professeur Bérard. Paper. Price, 25 francs. Pp. 307, with illustrations. Paris: Masson & Cie, 1925.

Monograph of especial interest to roentgenologists and surgeons.

The Diagnosis and Treatment of Tuberculosis of the Hip. By G. R. Girdlestone, B.M., F.R.C.S., Hon. Surgeon, Wingfield Orthopaedic Hospital, Oxford. Cloth. Price, $2.50. Pp. 94, with 60 illustrations. New York: Oxford University Press, 1925.

Practical consideration with a view toward orthopedic conservation.

Handbuch der experimentellen Therapie Serum und Chemotherapie. Ein Handbuch für die ärztliche Praxis und Klinik. Herausgegeben von A. Wolff-Eisner. Second edition. Paper. Price, 35 marks. Pp. 790, with 69 illustrations. Munich: J. F. Lehmanns, 1926.

Second edition of a standard foreign system of biologic therapy.

Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students. By Sir Thomas Lewis, M.D., F.R.S., D.Sc., Consulting Physician to the Ministry of Pensions. Sixth edition. Cloth. Pp. 131, with 55 illustrations. London: Shaw & Sons, Ltd., 1925.

Sixth edition of a standard work by widely recognized authority.

The Pathology of Tumours. By E. H. Kettle, M.D., B.S., Professor of Pathology and Bacteriology, Welsh National School of Medicine, Cardiff. Second edition. Cloth. Price, $5. Pp. 285, with 159 illustrations. New York: Paul B. Hoeber, Inc., 1925.

A manual for students, dealing with general biology, general pathology and special pathology of tumors.

Lecciones sobre Radiologia y Fisioterapia. Por el Dr. Filiberto Rivero, Profesor Titular de la Asignatura de Radiologia y Fisioterapia de la Escuela de Medicina, Universidad de la Habana. Paper. Pp. 270. Havana, 1925.

A Cuban view of modern roentgenology and physical therapy.

The Mosquitoes of Egypt. By T. W. Kirkpatrick, B.A., F.E.S. (Senior Entomologist, Ministry of Agriculture, Egypt). Anti-Malaria Commission. Paper. Pp. 224, with illustrations. Cairo: Government Press, 1925.

Official report of interest to entomologists.

Physiological Papers. Dedicated to Professor August Krogh, Ph.D., LL.D. Paper. Pp. 375, with illustrations. Copenhagen: Levin & Munksgaard, 1926.

Festschrift in honor of the fiftieth birthday of a Nobel prize winner.

The Harveian Oration: On Some Developments of Harvey's Doctrine "Omne Vivum ex Ovo." By Sir Frederick Mott, K.B.E., M.D., LL.D., Consulting Physician, Charing Cross Hospital. Cloth. Pp. 36. London: John Bale, Sons & Danielsson, Ltd., 1925.

Brief essay on heredity in mental disease.

Diseases of the Eye. A Manual for the Practitioner. By Henry Kirkpatrick, M.B. Cloth. Pp. 132, with 28 illustrations. Calcutta: Butterworth & Co., 1925.

Malpractice Case Against Chiropractor—Requirements

(Janssen v. Mulder (Mich.), 205 N. W. R. 159)

The Supreme Court of Michigan, in reversing a judgment entered on a verdict directed for the defendant, and at the same time granting a new trial, with costs to the plaintiff, says that the defendant was a chiropractor who had not complied with the law relative to the registration of drugless healers in Michigan. But, while a failure to comply with the registration statute might subject him to a criminal prosecution, such failure, coupled with a showing of treatment given, was not in itself sufficient on which to base a charge of malpractice. To maintain such an action, the plaintiff must show that the result complained of was due to negligence or unskilful treatment. While not registered, the defendant was a graduate of a chiropractic school. He assumed to treat human ailments only in accordance with the system taught in such school. This fact was well known to the plaintiff. The burden was therefore cast on her to show by competent evidence, not only that his treatment was injurious or not effective, but that the requisite care and skill was not exercised by him in administering it. It necessarily followed that such proof must be made by one engaged in treatment by similar methods to those employed by the defendant. With the merits of the several drugless systems of relieving human ailments, the courts have no concern.

This action was brought by the plaintiff, as administratrix, to recover the damages incident to the death of her daughter, aged about 7 years, the plaintiff charging malpractice by the defendant. The declaration alleged that the defendant knew, or should have known, that the child when brought to him was afflicted with diphtheria, and might fairly be said to charge malpractice by failure or neglect to ascertain the nature of her ailment before treating her. The defendant maintained an office to which people were invited to come for the relief of human ailments. He admitted that there were certain of such ailments which he did not profess to treat. It would seem to follow that he represented and held himself out to the public as possessing the necessary knowledge and skill to determine whether the ailment of the person brought to him was such a one as his treatment would probably relieve. If, as he testified, the class of practitioners to which he belonged does not assume to treat infectious, communicable diseases, they may not be relieved of civil responsibility if they neglect to exercise reasonable care and skill to ascertain whether the person seeking their services is so afflicted.

The defendant admitted that when the child was brought to him she had a fever and was suffering with a sore throat. While the plaintiff knew the nature of the treatment administered by the defendant, she did not know whether such treatment would be efficacious to relieve the ailment with which the child was afflicted. It was the duty of the defendant to use reasonable care and skill so to ascertain. While he insisted that he and others of his school of practice did not diagnose cases or treat diseases, and said that he knew nothing about germs or the symptoms of tonsillitis, quinsy or diphtheria, he did assume to relieve pain and suffering. The words used by him in defining that which he did, such as "palpate" and "adjust," did not change the nature of the act he assumed to perform. When he undertook to administer treatment to the child, he assumed the responsibility of determining whether the treatment he proposed to administer, and afterward did administer, was such as might reasonably have been expected to afford relief. So to determine, it was incumbent on him to use reasonable care and skill to ascertain whether the ailments were of the class to which his treatment applied. If not, it was his duty so to advise the plaintiff, in order that she might secure the services of one familiar with such ailments. His neglect to use reasonable care and skill to ascertain whether or not the child had diphtheria, if established to the satisfaction of the jury, would sustain the charge of malpractice made by the plaintiff. As bearing on the result to the child of such neglect, this court thinks that the plaintiff was entitled to show, if possible, that there is a customary and well known form of treatment used successfully by those of that particular profession who do profess to administer treatment to cure ailments of this nature, and that proper treatment by such a person would probably have afforded relief and saved the life of the child.

This court may take judicial notice that diphtheria is an infectious, communicable disease. It is so recognized by the laws of Michigan.

Malpractice Found in Case of Modeling Redressment

(Mortimer v. Keppler (N. J.), 130 Atl. R. 547)

The Supreme Court of New Jersey says that the plaintiff when 10 years old became afflicted with tuberculosis of both hips and was treated for two years at a hospital. The testimony indicated that in 1921 she was a healthy young woman, except that she had complete ankylosis of her left hip and partial ankylosis of the right, and a misplacement of the right leg. In December of that year she went to the defendant to have him secure her admission to a certain clinic. She told him about having been treated at the hospital for hip trouble. She gave her age as 18 years, although she was at the time about 24½ years old. That, however, appeared not to have been a deliberate misstatement, but owing to lack of knowledge and confusion as to her age. The defendant said that her condition was of a such a minor character as to make it unnecessary for her to go to the surgeon who conducted the clinic; that he could perform the operation himself. He directed her to have a roentgenogram made of her hips. After examining the roentgenogram, he said that he would manipulate the right leg, and would have to use a chisel and hammer on the left; that the operation was a minor one; that she would have to spend five days in the hospital, would be able to go back to work in two weeks, entirely cured and able to walk as well as he walked. He operated on her, Feb. 17, 1922. Immediately afterward she was in intense pain. Subsequently her right foot and lower leg became gangrened, and on April 1 her right leg was amputated at a point just above the ankle. The stump did not heal, and on November 1 there was a further amputation to a point just below the knee.

In one count the complaint charged negligence in an operation and treatment thereafter resulting in the necessity of an amputation of a portion of the plaintiff's right leg, and in another count charged negligence in the care and treatment of the plaintiff after such operation requiring a second amputation. Then, at the opening of the trial, the plaintiff was permitted to amend the complaint by adding a third count alleging an express contract to effect a cure and charging a breach thereof. The defendant answered, denying all negligence, and denying an express contract to effect a cure and any breach thereof. The plaintiff was given a verdict for $8,000 damages, which the defendant argued was against the weight of evidence because: (*a*) the plaintiff had misinformed him as to her age and as a result his diagnosis was based on the false assumption that the condition of her hips had endured for six and one-half years less than was the case; (*b*) the operation performed was a manipulation known as modeling redressment, and was not the operation of brisement forcé; (*c*) the plaster cast was not the cause of the circulatory disturbance; (*d*) the weight of the evidence was that there was some injury either to the femoral artery or to a large blood vessel; (*e*) the weight of the evidence was that there was no express contract to effect a cure. In deciding against setting aside the verdict, the court expresses the opinion that, as to the misstatement of age, there was ample evidence warranting a finding that the difference of six and one-half years was immaterial, while the court's consideration of the testimony led it to the conclusion that the verdict was not against the weight of the evidence.

It was urged that this language in the charge of the jury, "The operation being a so-called bloodless operation for the purpose of correcting an ankylosis or a partial ankylosis or stiffening of the right hip joint," was misleading because the operation was to obtain a better position of the right leg and contemplated the occurrence of ankylosis in the right hip. But, when the whole charge was read, the court does not think that reasonable men could have been misled. Again, it was contended that the following charge as to diagnosis was prejudicial because it left the jury to say whether the diagnosis was wrong:

> As to the matter of diagnosis—if you find that the defendant in this case did not use reasonable skill and diligence in diagnosing the plaintiff's ailment, and that this error in diagnosis led him to perform an operation which was improper under the circumstances, and that this operation resulted in an injury which brought on a gangrenous condition in the leg, necessitating the amputation of the lower portion, your verdict should be for the plaintiff.

There was a question as to whether the diagnosis was Perthe's disease, under which an operation could safely be performed, while, if tuberculosis was the original cause of the hip trouble, then such operation could not be safely performed. Under such circumstances the charge was proper.

Apparently, although not specifically, referring to an alleged attempt by the defendant to compromise the cause of action, the court says that, as to alleged incompetent evidence it thinks it was competent. It was not shown to have been made without prejudice, and was made before action commenced, and not at the solicitation of the plaintiff but of the defendant.

Vital Statistics Not Part of "Necessary Sanitation"

(Smith, Com'r, et al. v. State et al. (Ga.), 129 S. E. R. 542)

The Supreme Court of Georgia holds that, under a provision of the constitution of that state empowering the general assembly to delegate to any county the right to levy a tax "to provide for necessary sanitation," the legislature could not delegate to a county the right to levy a tax for the purpose of paying the fees of local registrars for services rendered under the vital statistics laws of the state, and that the statute authorizing their payment from the public funds of the county is unconstitutional and void. The court says that the duties these officials are required to discharge bear a very remote, if any, relation to the devising and applying of measures for preserving and promoting the public health, the removal or neutralization of elements injurious to health, and the practical application of sanitary science. Certainly the discharge of these duties is not necessary to the devising and applying of measures for preserving and promoting the public health. The gathering of these statistics may possibly be of some slight aid to investigators in devising methods of preserving the public health, but the court gravely doubts whether these statistics offer any help in discovering methods of preventing disease. Conceding, however, that they furnish some aid in research work looking to the discovery of means by which disease can be prevented, the court feels confident that the collection of these statistics is not such a means of providing necessary sanitation as was contemplated by the framers of the amendment to the constitution giving the power stated to provide for necessary sanitation. Clearly the purpose of the framers of the amendment, and of the people in adopting it, was to empower the legislature to authorize a county to levy a tax for the purpose of applying known and recognized methods of sanitation, such as vaccination to prevent smallpox, serums to prevent typhoid fever, diphtheria, scarlet fever, and the like, the purification of water, the destruction of the mosquito which produces yellow fever and malaria, and other well known methods of sanitation. This provision of the constitution must be given a plain, practical and commonsense construction.

Motions for a rehearing were made; but, after carefully considering them, the court does not think that a rehearing should be granted. It thinks that its decision in this case is sound. An additional reason for this is that there are county boards of health which "have full power and authority to adopt, enact, establish, and maintain all such rules and regulations, not inconsistent with the laws and constitution of this state and of the United States, as they may deem necessary and proper for protecting the health of their respective counties, and for preventing the introduction, generation, and spread of infectious and contagious diseases therein," except in incorporated cities or towns. These boards can "employ such officers, agents, or employees, and incur such expenses as they may deem necessary, which salaries, compensation, and expenses shall be paid out of the county treasury as are other county expenses." This county machinery is provided for necessary county sanitation. Then, there is a state board of health. The bureau of vital statistics is an adjunct or department of that board, which has full control of the registration of vital statistics. Under the constitutional provision involved, the court does not think that the legislature is authorized to provide for the payment of the expenses of a state department or state bureau out of county funds.

Nebraska State Medical Association, Omaha, May 11-13. Dr. R. B. Adams, McKinley Building, Lincoln, Secretary.
New Mexico Medical Society, Albuquerque, May 19-21. Dr. C. M. Yater, 310 N. Richardson Avenue, Roswell, Secretary.
New York, Medical Society of the State of, New York City, March 29-April 1. Dr. D. S. Dougherty, 17 W. 43d St., New York City, Sec'y.
Ohio State Medical Association, Toledo, May 11-13. Mr. Don K. Martin, 131 E. State Street, Columbus, Executive Secretary.
Oklahoma State Medical Association, Oklahoma City, May 18-20. Dr. C. A. Thompson, 609 Barnes Building, Muskogee, Secretary.
Oregon State Medical Society, Portland, April 1-2. Dr. F. D. Stricker, Medical Arts Building, Portland, Secretary.
South Carolina Medical Association, Sumter, April 6-8. Dr. E. A. Hines, Seneca, Secretary.
South Dakota State Medical Association, Aberdeen, May 19-20. Dr. John F. D. Cook, Langford, Secretary.
Tennessee State Medical Association, Memphis, May 11-13. Dr. J. F. Gallagher, Jackson Building, Nashville, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1924. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

31: 1-148 (Jan.) -1926

*Dried Human Milk. V. Use in Feeding of Premature Infants. P. W. Emerson and L. W. Smith, Boston.—p. 1.
*Bacteriologic Studies of Respiratory Passages. VI. Hemolytic Streptococci in Pharynx and Tonsils of Infants and Children. I. Pilot and I. H. Tumpeer, Chicago.—p. 22.
*Enlargement of Spleen in Measles. A. Bleyer, St. Louis.—p. 26.
*Congenital Cardiac Hypertrophy: Case. A. J. Scott, Jr., and A. H. Zeiler, Los Angeles.—p. 31.
*Calcification of Subcutaneous Tissue in Child (Calcinosis Universalis): Case. G. Wilens and J. Derby, Boston.—p. 34.
*Variations in Antiscorbutic Properties of Dry Milk. G. C. Supplee and O. D. Dow, Bainbridge, N. Y.—p. 41.
*Bronchial Asthma in Children and Young Infants. A. H. Rowe, Oakland, Calif.—p. 51.
*Is Development of Carpal Centers Delayed in Rickets? L. H. Goldberger, New York, and J. Mellion, New Haven, Conn.—p. 58.
*Blood Chemical Findings During Convulsions in Acute Hemorrhagic Nephritis. K. M. Metcalf and M. Moriarty, Boston.—p. 65.
*Diphtheria Following Tonsillectomy. A. Zingher, New York.—p. 72.
*Wheal Formation in Infants and Children. I. J. D. Pilcher, Cleveland.—p. 77.
*Id. II. J. D. Pilcher, Cleveland.—p. 96.

Feeding Dried Human Milk.—A series of thirteen cases is presented by Emerson and Smith in which infants were fed dried breast milk over periods of time ranging from four to 137 days. The evidence seems to prove that dried breast milk can be utilized as a substitute for fresh breast milk, and that it is particularly indicated in the case of premature infants and those with severe intestinal intoxications, for whom fresh breast milk is ordinarily indicated but is not available. The authors believe that by very slight further modification in the method of drying, a still better product can be obtained, which would be available at all times for indicated cases.

Hemolytic Streptococci in Tonsils.—Hemolytic streptococci were recovered by Pilot and Tumpeer in large numbers from the excised tonsils of twenty-five of twenty-eight children, aged from 2 to 6 years, and from the adenoids, in six of eleven children. From swab cultures of comparatively normal throats of seventy-five children, aged from 6 weeks to 10 years, hemolytic streptococci were found in sparse numbers in thirty-six. It is evident that these organisms reside normally in the tonsils and adenoids, and that from these sources the streptococcal complication in the course of other diseases commonly arises.

Enlarged Spleen in Measles.—Observations concerning enlargement of the spleen during the eruptive stage of measles were made by Bleyer in 396 cases. Of forty-seven patients who were examined the day before the rash appeared, the spleen was enlarged in 2 per cent; of fifty-eight patients examined on the first day of the rash, 24 per cent had enlarged spleen and of eighty examined on the second day, the spleen was palpable in 43 per cent. Enlarged spleens were found in 56 per cent of sixty-two patients examined on the third day and in 52 per cent of forty-nine patients examined on the fourth day of the eruption. This enlargement of the spleen was coincidental with the eruptive stage of this disease, both as to appearance and disappearance, the greatest enlargement both as to frequency and size being noted on the third and fourth days of the rash. The severity of an attack did not affect the incidence of enlargement of the spleen.

Congenital Cardiac Hypertrophy.—A baby, aged 5 weeks, was seen by Scott and Zeiler because of gastro-intestinal disturbance, dyspnea and cyanosis. The bony thorax was prominent anteriorly, with no pathologic changes in the lungs, and the heart showed no apparent abnormality. The lower edge of the liver was down to the level of the umbilicus. A tentative diagnosis was made of a congenital heart defect. The roentgenogram showed that the heart was enlarged to the right. The baby died two weeks later. At necropsy, the heart was found to weigh 55.4 Gm., and was 6.5 cm. (2½ inches) wide. There was marked hypertrophy of the ventricular musculature. The ductus botalli and foramen ovale were closed, and all the valves were competent. The left auricle was normal in size but the right was dilated. There was no causation to explain this condition other than that it was congenital.

Calcification of Subcutaneous Tissue.—A case of multiple calcifications of the subcutaneous connective tissue and fat, apparently unassociated with fat necrosis, is reported by Wilens and Derby. There were no indications suggesting the initial lesion. There was present a variable degree of obliterating endarteritis.

Antiscorbutic Properties of Dry Milk.—Experiments are recorded by Supplee and Dow which show that as high as 80 cc. of reconstituted spray process whole milk powder per day is sufficient to protect guinea-pigs from scurvy, when either of two common basal scorbutic rations are used. The data also show that dry milk made by the Just roller process, and stored in an atmosphere of air at room temperature for two years, has an antiscorbutic potency substantially equivalent to that reported for fresh milk produced at the same time of the year. It is concluded that neither the differences in the scorbutic basal ration nor the period of storage serves as an adequate explanation for the low antiscorbutic values reported for certain milk powders.

Bronchial Asthma in Children.—Seventy-seven cases of bronchial asthma occurring in patients under 10 years of age, and thirty-three in patients between the ages of 10 and 20, are reported by Rowe. Of these, 19.1 per cent gave a history of allergy on both sides of the family, and 51.8 per cent gave a unilateral family history of allergy. Ninety-five per cent gave one or more positive skin reactions; 71.07 per cent reacted to proteins of animal emanations. Reactions to feathers were obtained in 58.2 per cent, and pollen reactions in 40 per cent. The importance of food as a cause for asthma is emphasized by the fact that 53.6 per cent gave positive reactions. Wheat and egg proteins gave reactions in 22 and 21 per cent, respectively. Vegetables gave reactions in 31 per cent. The treatment was based on the protein sensitization revealed by skin tests and history. The treatment has given complete or nearly complete relief in 68.3 per cent; marked relief in 22.7 per cent; slight relief in 6.3 per cent, and no relief in 2.7 per cent. The relief obtained has necessitated continued adherence to diet, or to freedom from animal emanation and organic dust contacts, or to desensitization to pollens or other proteins, or finally to combinations of these factors.

Development of Carpal Centers in Rickets.—Forty infants with rickets and twenty-two without rickets were studied by Goldberger and Mellion with reference to the development of carpal centers. The evidence shows that the appearance of carpal centers in infants with rickets was later than in infants free from rickets. The development of second or subsequent carpal centers in infants with rickets was delayed, compared to their appearance when rickets was absent. The development of more than two carpal centers during the first six months of life was retarded in rachitic infants compared to nonrachitic infants. Although delayed, new calcification centers appeared during the active stages of rickets. Antirachitic treatment (cod liver oil, ultraviolet rays or yolk of egg) rarely brought about a development of carpal centers within a period of two months.

Blood Chemical Changes During Convulsions.—The principal features in the case reported by Metcalf and Moriarty were the changes which the convulsions induced in the sugar and in the alkali reserve, as well as the absence of marked changes in the other blood constituents investigated.

Diphtheria Following Tonsillectomy.—Zingher holds that it is strongly advisable that preliminary nose and throat cultures for diphtheria bacilli be taken as a routine before such operations as tonsillectomy and adenoidectomy. If the cultures are positive, a prophylactic dose of 1,500 units of diphtheria antitoxin should be injected, unless the patient has already been tested with the Schick test and shows a definite negative reaction or a negative pseudoreaction.

Wheal Formation in Children.—A study of wheal formation by the intradermal injection of codeine solution was made by Pilcher in a series of normal and sick infants and children. Wheal formation was lessened in all cases of edema studied regardless of the cause; namely, in nephritis, cardiac decompensation, leukemia, malnutrition from starch feeding, injury and in the local skin edema of serum urticarial wheals and saline infusions. Wheal formation is also lessened in certain ill defined skin infiltrations; namely, in cretinism and myxedema and in sclerema and scleredema. In nephritis without edema and in valvular and congenital heart disease without edema, even with considerable decompensation, the wheal formation is normal. In myocardial degeneration and in certain cases of severe prostration, wheal formation is diminished. A normal wheal reaction indicates an efficient circulation at the site of the wheal.

Wheal Formation in Rickets and Spasmophilia.—Pilcher states that low serum calcium and phosphorus, down to half the normal quantity, in infants with rickets or spasmophilia have no influence on the permeability of the minute vessels of the skin, as measured by the codeine wheal reaction.

Engineering Aspects of Oyster Pollution. R. E. Tarbett, Washington, D. C.—p. 5.
*Necessity for Changes in Ventilation Laws of United States. L. Greenburg, New Haven, Conn.—p. 13.
Rôle of Child Guidance Clinic in Mental Hygiene Movement. R. P. Truitt, New York.—p. 22.
Aids in Securing Better Registration. A. T. Davis, Dover, Del.—p. 25.
Improvements in Child Hygiene. C. H. Keene, Buffalo.—p. 29.
*Mediums for Estimation of Bacteria in Milk. J. F. Norton and M. Seymour, Chicago.—p. 35.
Year's Work in Food and Drug Field. F. C. Blanck, Washington, D. C.—p. 45.

Window Ventilation Better than Fan Ventilation.—Greenburg insists that the fan system developed on the basis of an erroneous knowledge of the need for ventilation should be abandoned (as applied to schoolrooms and auditoriums of less than seventy-five to 100 persons capacity), because it fails to produce satisfactory atmospheric conditions; because it leads to a high incidence of respiratory disease; because its first cost is excessive, and because its operation is poor and wasteful of heat. It should be superseded by the window system of ventilation with gravity exhaust which, comparatively, is highly efficient and inexpensive.

Mediums for Estimating Bacteria in Milk.—Norton and Seymour analyzed the bacterial counts obtained on five mediums from a series of samples of raw and pasteurized milk, particularly as regards uniformity of results. Veal infusion medium ranked first with meat extract agar and two dehydrated mediums second. Ayers' milk powder medium was less satisfactory. The results lead to the conclusion that standard meat extract agar, dehydrated nutrient agar and dehydrated peptonized milk agar are equally satisfactory.

Case of Decidual Reaction in Adenomyoma of Rectovaginal Septum. R. J. White, Fort Worth, Texas.—p. 112.
Case of Separation of Dorsal Vertebrae in Podalic Version and Extraction. W. R. Barney, Cleveland.—p. 116.

Treatment of Hyperemesis Gravidarum.—So important do Harding and Van Wyck consider the factor of dehydration in vomiting of pregnancy, that any such patient admitted to the wards of the Toronto General Hospital is at once treated, as a matter of routine, with 1,000 cc. of 5 per cent glucose solution in 1 per cent saline solution, given intravenously each day until diuresis is obtained. At the same time, rectal enemas of 200 cc. of 10 per cent glucose in physiologic sodium chloride solution are given three times daily, and at bedtime from 30 to 60 grains (1.95 to 3.9 Gm.) of sodium bromide are given in each enema for the first day or so. No attempt is made to feed solids by mouth, but fluids are urged even if the patient is vomiting freely, and she is encouraged and allowed to drink any liquid she may fancy, except tea, coffee, milk or cocoa. This treatment usually results, within three or four days, in such marked improvement that the patient is able to take food. It is not continued for a period longer than six days without effecting an appreciable clinical improvement.

Multiple Fetal Malformations.—A case illustrating multiple fetal malformations is reported by Mills and Walpert, which is said not to be duplicated in the literature. The chief points of interest are as follows: (*a*) Normal apparently full-term development of the upper half of the body; (*b*) absence of most of the anterior abdominal wall, its place being taken by a membrana reuniens; (*c*) abrupt termination of a relatively straight and normal spinal column at the lumbosacral junction with acute angulation, and lateral displacement of the deformed sacrum; (*d*) backward displacement and deformity of the pelvic girdle (pelvis inversa); (*e*) partial rotation and backward displacement of the buttocks, with extension of the legs up toward the occiput; (*f*) absence of one of certain paired organs and the rudimentary development of others, not all on the same side of the body; (*g*) hypoplasia of the thoracic duct; (*h*) practically complete development of the female generative tract from one müllerian duct, the other being rudimentary and widely separated; (*i*) complete development of the urinary system except for one kidney and its ureter; (*j*) persistent cloaca (failure of development of the urorectal septum); (*k*) association of a major form of fetal anomaly with placenta praevia centralis. A theory is proposed to account for many or all of the anomalies, based on an assumed congenital ascites due to a disturbance of fluid distribution occurring during growth. The incomplete development of the thoracic duct is possibly a contributing factor. An extensive bibliography gives all references to similar major malformations which could be found in the literature, together with a brief summary of the principal findings, when not mentioned in the title, and a letter indicating the library in which each has been found.

Cause of Onset of Labor.—The results of Kross' experiments show that in rats, at least, no labor inducing substances are produced during labor that have any appreciable influence on the course of pregnancy in the partner of a parabiotic pregnant pair.

Etiology of Impetigo Contagiosa Neonatorum.—Belding's observations corroborate the opinion of the previous investigators who find that a strain of *Staphylococcus aureus* of special virulence is the etiologic agent in impetigo contagiosa neonatorum. The cultural characteristics of the impetigo staphylococcus are practically the same as those of the ordinary staphylococcus.

American Journal of Tropical Medicine, Baltimore

Ascariasis in Preventive Medicine. E. B. Cram, Washington, D. C.—p. 91.

Protozoiasis in Temperate Zone.—Attention is directed by Smithies to the frequency with which protozoa may be demonstrated in the stools of patients who reside in the temperate zone. In the series studied (3,780 patients), one or more species occurred in 7 per cent of patients who presented themselves for the relief of digestive disorders.

Intra-Intestinal Thermal Therapy in Intestinal Affections.—The application of intra-intestinal thermal therapy by means of colonic lavage with salt solution at from 45 to 47 C., de Rivas says, has proved an efficient and safe procedure in the treatment of amebic dysentery and the removal of seat worms and other parasites of the large intestine. The application of the method in the form of duodenal or intra-intestinal lavage by means of the duodenal tube is likewise an efficient and safe procedure for the treatment of *Giardia* (*Lamblia*) infection and the removal of tapeworms, hookworms and other parasites of the same intestine. The method may be used also for the rapid elimination of acute poisoning with mercuric chloride, botulinus, mushrooms and trichiniasis. The practicability of the method and the principle on which it is based suggest its application in the treatment of sprue, intestinal auto-intoxication, the direct implantation of any desirable bacterial flora in the intestine and the intra-intestinal administration of drugs.

Trichomonas Buccalis.—*Trichomonas buccalis* has been found by Hogue only in the mouths of persons suffering with pyorrhea, acute gingivitis or abscessed teeth.

Antigenic Properties of Pollens.—Huber and Koessler demonstrated the antigenic property of pollens. While not itself proving the anaphylactic nature of pollen disease, this finding is believed to be highly significant for this interpretation.

Blood Serum from Carcinoma.—No specific substance was found by Daland in the blood serum of patients with carcinoma, which affected the rate of vesicle formation in paramecia in any way different from normal serum.

Electrocardiogram in Diabetes.—Studies were undertaken by Blitzsten and Schram to see in what way electrocardiographic tracings of diabetic patients differ from those of normal persons of the same age and sex. Notching of the main deflection of the electrocardiographic curves occurred more frequently in curves of diabetic patients than in curves of controls. Changes in the blood sugar concentration were associated with changes in the main deflections of the electrocardiographic tracings. Increasing the amount of blood sugar in dogs by etherization or by glucose injections caused an increase in the height of the Q-R-S wave, while a decrease in the amount of blood sugar produced a decrease in the amplitude of the Q-R-S wave.

Nonspecific Desensitization Therapy in Allergic Asthma.—Spangler cites a case which shows the clinical results of nonspecific protein desensitization following repeated intramuscular injections of venom protein (crotalin) solution in a case of bronchial asthma and hay-fever. The eosinophilic index seems to indicate that a state of antianaphylaxis has been maintained and that the patient has remained, as Spangler terms it, nonspecifically desensitized. The patient has remained entirely free from all asthmatic symptoms for eleven months.

Sino-Auricular Block.—Resnik would drop this term for "sino-auricular standstill," which is a more accurate expression of the condition as it is seen clinically.

Mononuclear Phagocytes in Peripheral Blood.—Three kinds of mononuclear phagocytes have been demonstrated by McJunkin in the circulating blood, two of which are found under normal conditions: (1) monocytes, mononuclear benzidine-positive phagocytes reacting to neutral red by the method of supravital staining; (2) lymphendotheliocytes, benzidine-negative mononuclear phagocytes that by the method of supravital staining react to neutral red (sometimes with arrangement of the dye granules in the form of a rosette); (3) hemendotheliocytes, benzidine-negative mononuclear phagocytes not reacting by the method of supravital staining to neutral red or reacting slightly to neutral red with the appearance of irregular dye cytoplasmic granules. The first two occur in human blood.

Etiology of Chronic Ulcerative Colitis.—A gram-positive diplococcus has been isolated by Bargen and Logan in 80 per cent of cases of chronic ulcerative colitis. This organism has been obtained in pure culture from the early lesions, in an acute exacerbation of the disease, from the depths of chronic ulcers, and occasionally from distant foci (tooth abscess or tonsils) elsewhere in the body. By the intravenous injection of the organism, lesions like those in human beings have been produced in rabbits and dogs, the lesions in the latter approaching the chronic stage of the disease in humans. From these studies, it would seem that the hope of control of this disease lies in (1) removal of the distant foci of infection; (2) immunization in some form against the causative organisms; (3) local and topical application and irrigation; (4) the empiric use of drugs, such as tincture of iodine; (5) the administration of some absorbent like kaolin by mouth, and (6) a nonirritating yet general diet.

Spindle-Cell Sarcoma of Heart.—In the case reported by Beck and Thatcher the clinical diagnosis of sarcomatosis was made by the presence of disseminated sarcoma nodules. Involvement of the heart with sarcoma was suggested by the subnormal blood pressure, rapid pulse rate, systolic murmur and an abnormal contour of the heart as seen in the roentgenogram. This was considered as a possibility, but a definite diagnosis of sarcoma, primary in the heart, was not made clinically. The tumor was situated in the wall of the left auricle. Numerous metastases were present in the muscles and subcutaneous tissues of the buttocks, scrotum, legs, arm and chest. Thirty-five cases of sarcoma primary in the heart are now on record.

Quinidine Therapy of Auricular Fibrillation.—Smith and Clark have had success in 61 per cent of their cases in the production of normal rhythm from auricular fibrillation by a one day plan of quinidine administration. One death occurred. The chief value of quinidine was found in the treatment of frequent paroxysmal auricular fibrillation when not associated with hyperthyroidism. The authors point out that it has many dangers and an extremely limited field of usefulness in the established case, and real benefit of any considerable duration is derived in only a small proportion of these.

Value of Icterus Index in Differentiating Anemia.—St. George and Brown have found that the icterus index, rationally interpreted by a modification of the Meulengracht method, is a distinct clinical aid in the differentiation of the anemias. Uncomplicated cases of hemolytic anemia have an index above the normal range. Uncomplicated cases of secondary anemia have a low index, generally below the normal range. Uncomplicated cases of pernicious anemia and the severe anemia simulating it in cases of carcinoma may readily be differentiated by the icterus index, in that the former has an index consistently above the normal (from 8 to 12.5) and the latter below the normal range. It is suggested that the icterus index may be used to follow the course of pernicious anemia and to determine, before the blood count falls, when it is advisable to give a transfusion, as well as when the patient is likely to improve spontaneously.

Concentration of Blood and Urine in Diabetic Toxemia.—In severe diabetic toxemia with marked dehydration of the blood, Bulger and Peters assert that the concentration of nitrogen and chloride in the urine is extremely low. With adequate treatment there is a rapid dilution of the blood and a rapid increase in the concentration of these substances in the urine. There is no direct relationship between the alterations in the blood and the urine and none of the changes appear to be significantly affected by the presence or degree of hyperglycemia or glycosuria.

Diameter of Red Blood Cells Differentiates Anemias.—A technic is described by Grosh and Stifel for the measurement of the diameter of red blood cells and for the construction of diameter curves, which is sufficiently accurate for clinical purposes and sufficiently simple to be used in a routine manner in examining any questionable blood spread. The diameter curves have been found of value in the differentiation of Addison's anemia in all its stages and of secondary anemia.

Renal Function with One Kidney.—Foster states that the decrease in renal tissue in a person with one kidney is only doubtfully revealed by kidney function tests when the findings are compared with those of a normal subject. The only test that shows *consistently* that there is a *limitation of function* is the ratio after giving urea. While the results of study of persons with only one kidney emphasize the limitations of diagnostic methods in the recognition of nephritis, they also suggest that caution must be exercised in endeavors to estimate the amount of tissue capable of function.

Relative Blood Volumes in Diabetes Mellitus.—Diabetes mellitus produces marked changes in water distribution and in the total water balance of the body. The degree of these changes, according to Foshay, is modified by the magnitude of the hyperglycemia and by the rate of onset. Their character is modified by vascular disease and renal permeability. Reduction of hyperglycemia (or the action of insulin) may produce either an increase or a decrease in the concentration and viscosity of the blood. The result in any given case depends on the antecedent water content.

Nephritis in Children.—In the 102 cases of glomerular nephritis in children reviewed by Clausen, infections played a prominent rôle in the causation. Chronic upper respiratory infections caused 33 cases; scarlet fever, 26; acute upper respiratory infections, 12; acute mastoiditis, 5; pneumonia, 10; diphtheria, 4, and chronic sinus infections, 4. There were 21 deaths in this group: from uremia, 10; pneumonia, 4; sepsis, 4; cardiac failure, 2, and pertussis, 1. As to treatment, if infection plays an important rôle in nephritis, eradication of the infection is indicated. In glomerular nephritis, the infection is usually an acute self-limited streptococcic infection. When it subsides, the patient recovers, often in spite of the treatment. When chronic focal infection exists, the question of operation naturally arises. Clausen has not seen any case cured by nasal sinus operations, but has seen benefit following removal of infected tonsils and teeth. Clausen has discontinued purgation and hot packs, has paid attention to infection, and has used diets considerably richer in protein and calories than before. Of twenty-eight cases of tubular nephritis, thirteen patients died. Sinus infection was certainly the cause of the disease in thirteen cases and probably so in four others. One point in treatment is stressed—not to limit the diet in these cases. The most striking benefit is seen when the causative nasal sinusitis can be cured. This can occasionally be accomplished by means of irrigations of the nares with alkaline salt solutions (sodium chloride, 0.75 per cent; sodium bicarbonate, 0.75 per cent). Instillations of mercurochrome, 1 per cent, appear to have benefited one patient.

Familial Diabetes.—Kern's patient, a Jew, aged 35, gave a familial history of diabetes. Three sisters, aged 17, 19 and 23, respectively, died in diabetic coma. In each instance the illness lasted only a few months. The patient's mother died in diabetic coma at 32, after an illness of two years. Her brother and one sister died in coma at about 40, each having been ill for several years. The remaining sister, now in her fifties, was also diabetic. Of the history of his grandparents the patient knew nothing, nor of the children of his mother's siblings. None of his father's family was diabetic. The patient's two children were living and well.

Quinidine Sulphate Ration in Auricular Fibrillation.—Talley relates the case of a woman, aged 52, who had auricular fibrillation and who kept very comfortable by taking a certain amount of quinidine sulphate every day. At present she is taking 6 grains (0.4 Gm.) of quinidine sulphate at 10 a. m. and at 10 p. m. to maintain a regular rhythm. Quinidine has rendered the pulse regular and kept her free from pain—an unusual complication in auricular fibrillation—and has abolished the recurrent attacks of acute fibrillation with rapid rate. In two other patients the maintenance of a regular rhythm by such a ration of quinidine regularly serves to keep the patients edema free.

Syphilitic Cirrhosis of Liver in Boy.—Congenital syphilis was the cause of the cirrhosis in Simpson's cases. The boy's father had died two years before with a diagnosis of syphilis, and the entire family—mother, sister and one brother—gave positive Wassermann reactions. The brother was a neurosyphilitic with marked dementia. Congenital syphilis in the patient was diagnosed at 8 years of age, when he had a sore mouth and was blind for two months, but improved under treatment. Two years later, he developed marked ascites, and 4,500 cc. of fluid was obtained by paracentesis. He was given a course of neo-arsphenamine and mercury and improved enough to enter the public school, but he was in bad shape. He appeared at first to respond to treatment, but developed epileptiform convulsions, passed into coma and died.

Hemochromatosis.—Pain was the chief complaint in Hartman's case. Physical examination showed unusually good nutrition, pale skin, atrophic rhinitis, and thyroid fulness, but nothing else of importance. The urine was very highly colored. The urinary pigments were not investigated. An attempt at biliary drainage caused hemorrhage from the biliary tract (?). The terminal period was marked by abdominal pain, nausea, vomiting, fever, hematemesis, prostration, anemia, petechial hemorrhages, and ecchymotic patches of the skin. There was a marked iron reaction of the tissues. There was no appreciable pigmentation of the skin or enlargement of the superficial lymph glands. A culture from the heart's blood was sterile. The condition was not recognized during life.

Diet Cure of Obesity.—The treatment in Evans' case consisted of diet alone. It was arrived at by calculating a diet for the patient's *ideal weight*, consisting of 1 Gm. of protein and 30 calories per kilogram, and such an amount of carbohydrate and fat that the ketogenic-antiketogenic ratio was 1 5 : 1. The menu was made up from these figures, eliminating as much of the fat as possible. This resulted in protein, 66 Gm.; carbohydrate, 79 Gm.; fat, 38 Gm.—a total of 922 calories each twenty-four hours. This was 14 calories for the ideal weight, 65 pounds (29.5 Kg.). She was given 10 grains (0.65 Gm.) of sodium bicarbonate twice a day.

Diabetes Mellitus; Gangrene; Pneumonia.—Kiefer, Brigham and Wheeler report a case of sudden infarction of the entire left foot occurring in a 19 year old boy, who was in diabetic coma complicated by pneumonia. The circulation did not return, and the condition went on to frank gangrene. Two days later the terminal phalanx of the fifth finger on the left hand suddenly became cold and black. However, the circulation gradually returned and almost all evidence of the infarction had disappeared within three days. The only evidence of pneumonia was a high temperature complicating the diabetic coma. However, within four days the boy developed a perfectly typical clinical picture of lobar pneumonia of the right base. Death occurred on the sixth day. Fifty-two cases from the literature are reviewed.

Ultraviolet Therapy in Pediatrics.—Wyman has found ultraviolet therapy a specific in treating rickets and tetany and a valuable therapeutic agent in treating tuberculosis of the mesentery and bronchial glands and tuberculous peritonitis.

Skin Reactions to Heat and Roentgen Ray.—Different areas on the abdomen of the same guinea-pigs have been exposed by Hawkins and Clark to suberythema doses of soft roentgen rays, to heat of intensity below the critical dose for the production of burns, and to both radiations in sequence. The only effect of exposure to roentgen ray or heat alone was a slight scaling of the skin. The results were the same no matter in which sequence the agents were applied

Parasitic Disease in Mother and Rickets in Offspring.—Observations made by Kawamura and Kasama show that young rabbits born of mothers affected with *Schistosomum japonicum* develop typical rickets Rickets can also be produced if young, healthy rabbits are infected It is natural to suppose that the rachitic changes are caused by the parasite itself. Since, however, a similar disease can be produced in the offspring when the mother is fed on egg yolk, the causation is not limited to the action of this parasitic toxin alone.

Etiology of Herpes Zoster.—Attempts made by Cole and Kuttner to inoculate rabbits, guinea-pigs and monkeys with material obtained from nine cases of herpes zoster proved unsuccessful.

Concerning Oneness of Bacteriophage.—Lytic filtrates active against *B. dysenteriae* Shiga, *B. coli*, *B pestis-caviae* and staphylococcus, respectively, proved to be differently affected by changes in hydrogen ion concentration. Bronfenbrenner and Korb are of the opinion that, as these differences in individual resistance persisted, notwithstanding the repeated passage of lytic filtrates through cultures of bacteria other than those against which they were primarily active, the fact seems to offer evidence in favor of a multiplicity of bacteriophages.

Tumor Susceptibility and Heredity.—Lynch reports that two strains of mice, one with a high, the other with a comparatively low, incidence of spontaneous tumors of the mammary gland, when painted between the shoulders with coal tar extract, developed tar tumors with about practically identical frequency. No hereditary differences in the response of the skin to tar painting were demonstrable in two strains of mice manifesting markedly different percentage incidences for spontaneous mammary growths. Mice from which spontaneous mammary tumors had been removed were treated with tar. The percentage incidence of the resulting tar tumors was similar to that met with in the controls, except, possibly, in the case of such animals as showed a recurrence of the spontaneous growth. In them the development of tar tumors seemed to be delayed and possibly prevented. The numbers involved are too small to be conclusive.

Differentiation of Human and Anthropoid Blood.—The serologic differences between man and the lower monkeys appear to be no greater than those between the anthropoid apes and the lower monkeys. These findings confirm the opinion that the anthropoid apes do not rank in the genealogic tree between lower monkeys and men.

Blood Groups in Anthropoid Apes.—The bloods of twenty-one anthropoid apes were examined serologically by Landsteiner and Miller. It was found possible to assign each to one of the four human blood groups. The iso-agglutinogens of the anthropoids were found to be identical with those of human blood. These very same factors could not be demonstrated in the blood of the lower monkeys. In the blood of fourteen chimpanzees examined, only the iso-agglutinogen A has been found, whereas both A and B were present in the blood of six orangs. The significance of these findings for the knowledge of the human blood groups is discussed.

Special Serologic Factors in Blood.—Serologic studies on the bloods of thirty-six species of lower monkeys have shown that there exists a correspondence between the distribution of a certain hemagglutinogen and the place of the species in the zoological system. It would seem from these findings that a genus, perhaps even a family, of animals may be characterized by a special serologic factor. The factor found in the lower monkeys is not identical with the one in the erythrocytes of the anthropoid apes and man.

Akiyami Caused by Leptospira.—From the results of an etiologic study of the disease known as akiyami, which prevails in the Shida district of Shizuoka province, Koshina, Shiozawa and Kitayama conclude that akiyami is an infectious disease caused by a leptospira. The leptospira causing akiyami is very difficult to differentiate morphologically from *L. icterohaemorrhagiae* and *L. hebdomadis.* The strains of leptospira isolated from cases of akiyami are of two types. One type, isolated from three of sixteen cases, is highly virulent for guinea-pigs and is serologically distinct from *L. icterohaemorrhagiae* and *L. hebdomadis.* It is termed the A type. The type obtained from the other cases is less virulent for guinea-pigs and is serologically identical with *L. hebdomadis.* This is termed the B type. The field mouse (*Microtus montebelli),* which harbors *L. hebdomadis,* has also been found to harbor the A type of akiyami.

Influence of High Protein Diets on Kidneys.—Seven groups of rats were fed by Miller on diets containing protein varying in amount from 1.36 to 40.13 per cent derived mainly from grain, casein, meat and milk with carbohydrate, fat and vitamins. From a number of animals one kidney was removed to double the load on the remaining one. The time of feeding was from nine weeks to six months. Blood uric acid, blood urea nitrogen determinations, and microscopic examinations of the kidneys revealed no evidence of kidney damage. There was evidence of kidney hypertrophy, consisting of increased weight of the kidney, large diameters of the capillary tufts, convoluted tubules, and kidneys in the animals receiving high protein diet. The nephrectomized animals that ate high protein had no kidney changes, except hypertrophy, and this amounted to an increase in weight of an average of 0.54 Gm., or 85 per cent of the average weight of the right kidneys of the controls.

Hexylresorcinol.—Leonard and Frobisher emphasize that the successful application of hexylresorcinol in the treatment of chronic infections of the urinary tract depends on the strict observance of four factors, all of which bear a distinct relationship to the surface tension of the urine. (1) The dosage must be adequate (0.6 Gm. three times daily). (2) The fluid intake must not be increased, for this not only dilutes the active hexylresorcinol in the urine but renders even that dilution less effective than it would be otherwise, by raising the surface tension. (3) Sodium bicarbonate must be avoided, for this drug raises the surface tension of the urine so markedly as to rob it of its bactericidal properties. (4) The course of treatment should be uninterrupted and sufficiently prolonged.

Sterilizing Urinary Tract.—Experimental and clinical work has convinced Young that mercurochrome-220 soluble may be used intravenously without fear of serious or continuous damage to the kidneys. He feels so sure of this position that he has not hesitated to give mercurochrome intravenously even when albumin, casts, pus cells and bacteria have been present in large numbers in the urine.

Brain Tumors in Children.—One hundred and twenty-five cases of brain tumors in children are analyzed by Critchley. These cases represent 8.2 per cent of all cases of brain tumor seen during a given period. In fifty-nine cases the tumor was situated in the pons or cerebellum, in thirty-four in the cerebrum and fourteen were classed as "pituitary or suprapituitary." The symptomatology is discussed.

Plantar Lines in Mental Defectives.—Brushfield studied the foot in 618 mongol and other varieties of mentally defective children. He noted that in degenerate persons there appears to be a tendency for the primitive condition of the sole to be reproduced, with deeper markings, and to persist for some years later, up to the fourteenth year. The oblique plantar line was found to be an almost constant character of the mongol, and its importance lies in the fact that it underlines the simian quality of so many of the mongolian features met with in this variety. The marked feature in the foot of the mongol is that he possesses, in addition to this line, a wide gap between the first and second toes. If the finger is pressed on this line it appears to come directly in contact with the head of the metatarsal on each side. As these plantar lines or folds occur so frequently and persist so late in mental defectives they should always be looked for, and when present should be regarded as a stigma.

Phenobarbital Causes Bullous Eruption.—One gram every day for fourteen days was all the phenobarbital Weber's patient had taken. Nevertheless, she developed a very severe rash on the face and body. The girl did not feel ill, in spite of the fact that she was almost completely covered from head to foot with a florid morbilliform eruption (slightly purpuric in parts), the face, about the eyes, nose and lips, being especially affected. In addition there were numerous bullae. The most striking feature of the case was that the unbroken bullae contained a deep ochre yellow serous fluid, and the macerated epidermis constituting the wall of the collapsed bullae was similarly stained. The sclerotics were not markedly jaundiced, but the serous content of the bullae was found to give a strongly positive biphasic van den Bergh reaction for bilirubin; the indirect reaction was stronger than the direct reaction. These symptoms persisted for about three weeks. Copious desquamation took place.

*Bactericidal Effect of Ultraviolet Rays. A. Eidinow.—p. 35.

Radium Treatment of Actinomycosis.—Heyerdahl reports the clinical history and results of radium treatment in twenty-one cases of actinomycosis faciei and colli, some of these very serious cases, at the Riks Hospital, Oslo, Norway. In all cases the diagnosis was confirmed microscopically. In the great majority of cases, gamma rays of radium were employed, from concentrated preparations of radium, the radium rays being filtered through 1 or 2 mm. of lead. The result of the treatment has in all cases been cure without relapse, in the majority of cases with fine cosmetic results.

Bactericidal Effect of Ultraviolet Rays.—Cultures of many bacteria and pathogenic organisms are rapidly destroyed by direct exposure to ultraviolet rays. Eidinow asserts that this bactericidal action can also occur when a very thin film of blood containing bacteria is exposed to sources of ultraviolet rays. When photosensitizers, such as eosin and hematoporphyrin, are added to bacteria, the direct bactericidal action can take place on exposure to the visible rays. The direct exposure of defibrinated blood to sources of ultraviolet rays destroys the bactericidal properties of the "irradiated blood."

Artificial Light Treatment in Surgical Tuberculosis.—Gauvain stresses the fact that while general light baths will often convey to a patient a sense of well-being and even of exhilaration—in other words, produce a marked temporary tonic effect which may be reflected in local improvement more often than not—it is not a specific but merely a transitory reaction, the benefit of which becomes later less apparent. Just as the claim that "the sun will cure all forms of surgical tuberculosis" is quite untenable and is certain eventually to dishearten many sufferers and bring discredit on those who make that claim, so undue optimism in artificial light therapy will have an inevitable reaction. It is eminently desirable to use this method of treatment in surgical tuberculosis in suitable cases, but it should be regarded merely as an adjuvant method of treatment, as often a useful aid, but in no sense as a specific treatment. Gauvain urges that artificial light treatment should be undertaken only under informed medical guidance and with full and adequate equipment, manipulated by specially trained nurses.

Effect of Winds on Phthisis.—After twenty-five years of careful research, carried out by several methods and in many areas, into the effects of strong prevalent rain-bearing winds on the commonness and on the course of phthisis, Gordon says it can be asserted confidently: (*a*) that populations exposed to these winds suffer more (often much more) from phthisis than populations sheltered from them, and (*b*) that phthisis patients living in localities exposed to these winds have a higher (often a much higher) death rate and a lower (often much lower) recovery rate than patients living in shelter from them.

Hemochromogen Crystal Test for Blood.—To test for hemin crystals, Kerr and Mason prefer Sutherland's method. For the production of hemochromogen crystals, the best procedure is to use Takayama solution no. 2. In the majority of cases, especially with fresh stains, if care is exercised, there is no difficulty in obtaining hemin crystals. The hemochromogen crystal test, however, possesses certain advantages, simplicity of technic being obtained in the cold by simply adding the Takayama solution. If it is desired to heat the slide, there is no danger of overheating as there is in the case of hemin crystals. The crystals are large, easily seen and are of a very characteristic appearance and color. The nature of the crystals may be confirmed by means of the spectroscope.

Diagnostic Test in General Paresis.—Harris asserts that the acetic anhydride-sulphuric acid test on the cerebrospinal fluid in cases of general paresis is positive in almost every case (97 per cent), and hence is almost as reliable as the Wassermann reaction in this condition. It is negative in almost every other type of mental disorder, except certain cases of neurosyphilis (other than general paralysis of the insane). It is a test which can be performed with great ease and rapidity and therefore is of definite value to the clinician.

Somatic Origin of Malignant Disease.—Crowther advances the theory that malignancy is not a property of cancerous tumors but a suicidal reaction of the body to an innocent hyperplasia. The reaction is suicidal because the hyperplastic cells are really part of the body, and the specific poisons generated to destroy the tumor are almost equally poisonous to the body at large. Sarcoma probably differs in its nature from carcinoma; here the disease process seems more complex, but the essential nature of malignancy is probably the same. It follows that if the body can be led to disregard the tumor, the malignant process will stop and the patient will be cured, except that the original hyperplasia will remain. This result might be achieved by blocking the afferent nerves of the part.

Rectus Transplantation in Ventral Hernia Operation.—Nuttall advocates shortening, overlapping, or transplanting the recti as a useful adjunct in the treatment of all cases of ventral hernia. The rectus muscles are detached from the pubes and can be shortened, if required, by making a tuck; they are then sutured to the symphysis, or can be overlapped and sutured with kangaroo tendon to the pubes after holes are drilled in the bone.

Treatment of Chronic Varicose Ulcer.—Bertwistle treats these cases by applying silver nitrate to the edge of the ulcer to destroy the granulations, and then covering the ulcer with gauze, soaked in a saturated solution of picric acid or by dusting with iodoform.

Anatomic Changes in Hearing Apparatus of Deaf Mutes.—A deaf-mute, aged 56, died of malignant disease of the stomach. Gray and Nelson secured the temporal bones and subjected the entire hearing apparatus to a careful and minute examination. First of all, there was no evidence of any hereditary tendency to deafness or deafmutism in the patient's family history. On the other hand, the fact that the patient had a brother who was a deaf-mute would indicate that some factor (possibly syphilis) had occurred in one or both of the patient's parents which had caused deafmutism in two of the children. As to the ear itself, there had been no arrest of development of the cochlea due to a toxic lesion or other cause occurring in intra-uterine life. It is suggested that the condition in the inner ear is indicative of repair occurring at a period of fetal life when the tissues are susceptible of repair, of a degree far more complete than is possible in postnatal life. Development has again proceeded, but it has not been of the ordinary type. It resembles that of the reptile or of the bird. The development of the nervous apparatus, however, does not seem to have been interfered with, and there is no reason to doubt that the impulses have been transmitted along the nerve paths, so far as microscopic examination can give information. Owing to the abnormal development of the cochlea, these impulses have been abnormal and consequently have not been appreciated in the ordinary manner by the higher cerebral apparatus.

Results in Laryngectomy for Cancer of Larynx.—Of the fourteen cases reported on by Colledge, seven patients are alive and well without recurrence at periods of from four years to not less than one year after the operation. Three have died from recurrence. Two died from bronchopneumonia shortly after the operation, and one from embolism a month later. One died suddenly in the street six months after the operation.

Melanoma of Hard Palate.—In Patterson's patient, a woman, aged 51, the tumor was known to have been present for ten years. It was a pigmented mass occupying the greater part of the hard palate, and extending slightly onto the soft palate. Enlarged glands were palpable below the angle of the jaw on the left side. The tumor was removed from the palate by dissection; this was followed by vigorous diathermy, the result being that a large portion of the hard palate subsequently came away as a sequestrum. A few weeks later a block dissection of glands was carried out on the left side of the neck, the greater part of the sternomastoid muscle being removed. The patient was subsequently treated by roentgen ray. A year later the glands below the angle of the jaw on the right side were seen to be enlarged. They were removed. For three years there was no sign of recurrence, then a swelling was noticed over the lower part of the chest on the left side. The patient is still under observation.

Endometrioma.—Herd's discussion of the etiology, pathology and clinical importance of certain glandular tumors arising within the pelvis, and more especially in the uterus and ovaries, is based on a study of more than 200 specimens. It is apparent that there are many different ways in which extra-uterine endometriomas may arise.

Fate of Graafian Follicle.—Shaw asserts that only a small percentage of graafian follicles found in the ovary at birth undergo ovulation. The majority become atretic. The atretic structures derived from the follicle are the corpus atreticum, corpus candicans, corpus fibrosum and corpus restiforme.

Treatment of Fibromyoma of Uterus.—Martindale analyzes 252 cases treated either by surgical operation or intensive roentgen-ray therapy. He feels that both methods have their uses, and the choice must be left to the gynecologist who has not only diagnosed the actual pelvic condition but has also obtained a knowledge of the physique and power of resistance of his patient.

Unusually Large Uterine Tumor.—The tumor in Stevens' case weighed 47 pounds and 5 ounces (21.4 Kg.). It was drawn out of the abdomen by means of a block and tackle, and the operation of subtotal hysterectomy was completed in thirty-five minutes. There was no postoperative shock.

Preservation of Insulin.—Trocello and Cruto insist that insulin be kept in solid form because, as shown by experiments, it does not undergo any alteration at a high temperature, and can be preserved for an unlimited length of time. The cause of the difference in preservation of insulin in liquid form lies in the fact that a hydrolysis of the product causes a deterioration in its pharmacodynamic properties.

Protection of Head Against Sun's Rays.—Corson believes that there is a tendency to attach an exaggerated value to the penetrative power of the sun's rays in tropical Africa. He says that a light form of hat with good reflecting power, such as a Panama, may safely be used instead of a helmet, at least when the circumstances of daily life do not require prolonged exposure to the sun.

*Familial Neurosyphilis with Apparently Healthy Parents. A. G. Duncan.—p. 179.

Mercurochrome in Treatment of Acute Bacterial Infections.—Dudgeon has used mercurochrome-220 soluble intravenously in 150 cases of acute bacterial infections subsequently to, or instead of, mercuric chloride, has has found it to be of definite value. Mercurochrome dissolved in saline solution hemolyzes red blood corpuscles, but in the presence of blood serum or blood plasma the hemolytic activity is considerably reduced. With washed red cells, hemolysis occurs with a dilution of 1:2,000 in saline in vitro, while Dudgeon employs for intravenous inoculations strengths of 1:200, 1:500 and 1:750 in saline solution without ill effect. He has given daily intravenous injections of mercurochrome for five days without observing any complications which could be credited to it.

Transfusion of Defibrinated Blood.—The disadvantage of transfusion with citrated blood is the frequency with which "reactions," often mild, sometimes serious or even fatal, follow the introduction of the blood. In thirty-four consecutive cases in which transfusion was done by Platt with defibrinated blood, no such reaction occurred.

Blood Transfusion Apparatus.—Moll advocates the use of record syringe needles for both the donor and the recipient.

Aneurysm of Sinus of Valsalva.—In the case reported by Sheldon, intracardial rupture of the aneurysm was prevented by the presence of a coexistent adherent pericardium, probably of rheumatic origin. The aneurysm ruptured in the midline of the sternum at the level of the sixth cartilage. The sinus of Valsalva by the anterior cusp was expanded to form a saccular aneurysm. The aorta showed patches of syphilitic aortitis but was otherwise normal.

Familial Neurosyphilis.—Duncan's patient was one of six children, and the mother had had one miscarriage at the sixth week. The patient and a brother had dementia paralytica. Another brother had headaches and a positive blood Wassermann reaction. While both parents were negative in every way, the mother's father, two uncles and two brothers died in a mental hospital.

*Nerve Irritation and Aortic Lesions. R. C. Shaw.—p. 203.
*Can Insulin Produce Even Partial Cure in Human Diabetes Mellitus? G. A. Harrison.—p. 223

Heart Failure with Normal Rhythm.—One hundred unselected cases of severe congestive heart failure with normal cardiac rhythm, the patients being between the ages of 20 and 70, are described by Parkinson and Clark-Kennedy. Eighty-four patients have died and forty-eight necropsies were obtained. The pathologic condition to which failure was attributable proved to be cardiovascular hypertrophy (high blood pressure) in twenty-six, cardiovascular syphilis in twenty, chronic pulmonary disease in nineteen, chronic rheumatic heart disease in seven, acute or chronic rheumatic endocarditis in four, atheromatous coronary occlusion in four, and congenital morbus cordis in one. Apart from these cases, in two the failure was due to chronic rheumatic heart disease and high blood pressure, in two, to chronic rheumatic heart disease complicated by infective endocarditis, and in one to high blood pressure complicated by cardiovascular syphilis. In the remaining fourteen, the pathologic basis of failure was uncertain. Only seven patients in the whole series subsequently acquired auricular fibrillation; two of them had chronic rheumatic heart disease; in one case it was attributable to past rheumatic infection, and in three, apparently to the heavy administration of digitalis. Evidence is adduced showing that normal rhythm likewise persists in heart failure, due to cardiovascular hypertrophy (high blood pressure), chronic pulmonary disease, syphilitic aortic and coronary disease, and atheromatous occlusion of the main coronary arteries, as well as to congenital malformations. In these conditions the heart muscle is not primarily diseased Evidence is also given proving that in hyperpiesia (cardiovascular hypertrophy) the blood pressure sometimes falls to normal during the progress of failure. Cases with no apparent clinical cause of failure are described and classified as "primary myocardial." Necropsy showed that in some of these the failure was due to previous high blood pressure (systemic cardiovascular hypertrophy) and in others to atheromatous occlusion of the main coronary arteries. In none of them was it due to chronic myocardial inflammation or degeneration. No example in the whole series was seen of failure with normal rhythm from nonrheumatic primary myocardial disease or degeneration. It is suggested that the pathologic basis underlying nonrheumatic auricular fibrillation is likely to be found in a generalized change in the auricular muscle, such as might result from chronic inflammation, toxemia, or diffuse coronary sclerosis. Of the patients with high blood pressure, few presented clinical evidence of renal disease. Necropsies showed that a correspondingly small minority had severe primary nephritis, though many had some degree of associated chronic interstitial nephritis. The average duration of life from the onset of edema in the eighty-four cases ending in death was only eight months.

Erythremia Caused by Rectogenital Pouch Tumor.—Erythremia of intense degree without splenic enlargement is rare, but in the case cited by Barnes, Thomson and Lamb it was due to a diffuse growth scattered throughout the lung alveoli, and containing unstriped muscle tissue. The primary growth was a tumor of the rectogenital pouch which had been sarcomatous. This is said to be the first case of the sort on record.

Significance of Blood Fats During Treatment of Diabetes.—Data are given by White as to the reaction of the blood fats in thirteen cases of diabetes mellitus under treatment, in all of which, except two, treatment at some time was with insulin. The possible factors influencing the blood fat level are considered and the difficulty of obtaining any definite correlation between them noted. The necessity for further observation, if blood fats are to be used for prognosis, is emphasized.

Nerve Irritation and Aortic Lesions.—Experimental work done by Shaw with the idea of inducing vascular changes by irritation of nerve supply, in this instance the cardio-aortic, indicate a possible relationship between aortic disease and nervous phenomena, for example, such as occur in angina pectoris.

Does Insulin Effect Cure in Diabetes?—As a result of observations lasting from eleven to eighteen months on five selected cases of diabetes mellitus, no evidence was obtained by Harrison of even a partial remission of the disease. The daily intake of carbohydrate, protein, fat and calories remained fixed throughout. The dose of insulin was adjusted to the fixed diet according to the results of estimations of the blood sugar content. All five patients needed as much or slightly more insulin at the end of the observations as at first.

*Experimental Leprosy in Monkeys. J. Reenstierna.—p. 78.

Hypersensitiveness in Experimental Tuberculosis.—Boquet and Nègre inoculated guinea-pigs and rabbits with tubercle bacilli. This was followed after a certain time (Debré's ante-allergic period) by a manifest reaction of the animals to injections of tuberculin or bacilli bodies. This sensitization did not seem to be connected with the appearance of specific tubercles, as it occurred with nonvirulent tubercle bacilli, killed bacilli or their proteins, as well as with living and virulent bacilli. The hypersensitization usually coexisted with immunity, somewhat preceding the latter. In animals injected with killed bacilli, paratuberculous or avian tubercle bacilli, the hypersensitization did not seem to be accompanied by any appreciable immunity. Evidently immunity and hypersensitivity are two distinct conditions in organisms infected with tubercle bacilli.

Experimental Leprosy in Monkeys.—Reenstierna induced leprosy in five of seven monkeys inoculated with bacilli from patients with untreated leprosy. Characteristic nodules appeared after an incubation period of from thirty-seven to forty-five days; they persisted from forty to sixty-two days. One nodule still persists up to seven months since the inoculation. The clinical course and histologic aspect of the nodules were identical with those in man. Reinoculation, made about seven months after clinical recovery, showed that there was no immunity. Emulsions of these nodules, injected in new monkeys, did not induce the disease. Several colored illustrations are given.

Congenital Syphilis in a Tuberculous Girl. W. Mikulowski.—p. 36.
*Honey in Infant Feeding. J. Comby.—p. 46.

Hydatid Cyst of the Lung in Children.—Morquio has now a record of 112 cases of hydatid cyst of the lung in children. The disease occurred chiefly in rural districts and was more frequent in boys than in girls, but never was observed under the age of 4 years. Most of the children were from 8 to 12 years old. Sometimes it was associated with echinococcosis of the liver; in most of the cases it was primary and isolated; usually one cyst; rarely two or three, or even four. The cysts developed in one or both lungs. This suggests that the parasite may have entered by way of the respiratory tract, not always by the digestive tract. The affection may be confounded with pulmonary tuberculosis or pleurisy. The diagnosis is easy if, regardless of physical signs and hemoptysis, the general condition remains good. Roentgenograms may sometimes reveal the presence of the cyst; exploratory puncture is more valuable. The cyst developed in three or four years, gradually extending from the center of the lung to the periphery. It did not show any tendency to generalization. The cyst was expelled in most of the cases with a spontaneous vomica. Its rupture followed a trauma or general disease, especially of the respiratory apparatus. It is possible that fatigue or emotion may also induce rupture of the hydatid cyst. After the vomica the cure was manifest in 90 per cent at least, and the recovery seemed to be definite. Medical treatment is of no avail; expectant treatment should be preferred even to an operation. He cured one grave case by an artificial pneumothorax. The large cavity became rapidly obliterated.

Honey in Infant Feeding.—Comby thinks that honey, so commonly used in the old times, is now forgotten too much. He emphasizes its content in easily assimilated carbohydrates, vitamin B, calcium and iron phosphates, also formic acid. It has laxative properties, and keeps indefinitely. Therefore he recommends honey especially in infant feeding and for all children. He refers to King's account of a Swiss sanatorium, where weakly infants are fed with warm raw milk with honey. The amount of the latter is gradually increased from half a teaspoonful to a tablespoonful, twice a day. No other food is given. About 200 infants thus treated showed a marked increase of weight and hemoglobin. The tolerance for the honey was perfect.

*The Phrenic Sign in Appendicitis. M. O. Iliescu.—p. 96.

The Phrenic Sign in Appendicitis.—Iliescu calls attention to what he says is a new sign of appendicitis, namely pain from gentle pressure on the right phrenic nerve in the neck. The tip of the finger is applied to the center of the triangle formed by the two branches of the right sternocleidomastoid muscle. The sign was positive in all his 150 cases of acute or latent appendicitis. It was negative in suppurations of the adnexa, and in catarrhal salpingitis. A positive phrenic sign with right adnexitis revealed the coexistence of appendicitis. The sign was positive with gastric and duodenal ulcer secondary to appendicitis, and also in peritonitis connected with appendicitis. It disappeared under ice applied to the appendix, and reappeared with the flaring up of the disease. The disappearance of the sign was definite after operation. The tenderness may be ascribed to an ascending right lymphangitis, irritating the phrenic nerve on that side.

Erythromelalgia. C. Achard.—p. 69.
*Syphilis of Salivary Glands. R. Girard and I. Trigher.—p. 72.

Syphilitic Disease of the Salivary Glands.—Girard and Trigher report two cases of secondary syphilis with involvement of the salivary glands. There was apparently no connection with lesions of the mouth, since in one instance the buccal mucosa seemed healthy. Trismus, enlargement of the parotid glands, with or without that of the submaxillary glands, and excessive discharge of saliva, to such an extent as to prevent sleep, were the main symptoms. Under combined neo-arsphenamine and mercury treatment the whole clinical picture subsided in a few days.

*Symptomatic Hemophilia. P. Emile-Weil and Stieffel.—p. 55.
Epidemic Form of Pneumonia. Armand-Delille and Vanbockstael.—p. 59.

Spinal Syphilis of Pseudotumor Form.—Sicard, Haguenau and Lichtwitz report four cases of spinal syphilis in which the lumbosacral region was affected in two, the lumbodorsal in one, and the dorsal in one. The cerebrospinal fluid in two cases was yellowish, while in the others there was an increase of albumin with lymphocytosis. Roentgenograms, under iodized oil control, revealed the presence of meningeal adhesions in the two with xanthochromia, but under specific treatment the adhesions disappeared. The pathologic signs of the cerebrospinal fluid subsided only very slowly under intensive specific treatment. The patients were from 26 to 46 years old.

Migraine Associated with Tetany.—Parhon and Werner describe a third case of ophthalmic migraine associated with tetany spasms. This patient was a woman, aged 28. The coexistence, among other signs and symptoms, of decayed teeth, pruritus, and falling out of the hair suggested a possible thyroparathyroid insufficiency, with subsequent disturbance of the calcium metabolism. There was only transient improvement under thyroid treatment. Parathyroid extract did not display any favorable effect, but this may be observed likewise in experimental parathyreoprival tetany.

Absence of Xiphoid Process and Congenital Syphilis.—Sézary, Vibert and Godel's observations include 226 children, aged from 4 to 14 years. Absence or extreme atrophy of the xiphoid process was found in 20 per cent; in 58 per cent of the children with congenital syphilis. This deformity existed also in both father and mother in one instance; in the mother alone in eleven; in brothers or sisters in five. It was more frequent in girls than in boys. It is possible that atrophy of the xiphoid process, passing from generation to generation, will finally cause its disappearance in man.

Grave Hemophilia with Jaundice.—Emile-Weil and Stieffel treated a woman, aged 27, with jaundice from gallstones and cholangeitis. Examination revealed a hemogenia-hemophilia syndrome, the coagulation time being over three days, the bleeding time about fourteen minutes. Three transfusions of 300, 350 and 250 cc. of blood were given to prepare for the indispensable operation on the common bile duct. This transformed the patient's blood; the coagulation time became gradually reduced to thirty minutes and the bleeding time to from six to fourteen minutes. The gallstone operation was then ventured, and she made a smooth clinical recovery without excessive hemorrhage. The acute and curable hemophilia was evidently symptomatic, from the infection and obstruction in the biliary apparatus. They know of two other instances of symptomatic hemophilia, one in their own experience (fatty hypertrophic cirrhosis in a tuberculous patient), and Paisseau, Ceyla and Hamburger's case, occurring in syphilis and cured by specific treatment.

Action of Heating on Hemolytic Power of the Blood.—Holding the forearm for an hour in water at a temperature of 40 to 50 C. (122 F.) materially reduced the hemolytic power of the blood serum in two patients with hemoglobinuria. A ligature was applied above the elbow, as for the Ehrlich test. Emile-Weil and Stieffel believe that this influence of heat might possibly be utilized in treatment of hemoglobinuria.

Intestinal Flora of Infants Under Mixed Feeding.—The stools of breast-fed infants, given also cow's milk, contained putrefaction microbes. Their amount paralleled that of the casein in the milk. This was observed with sterilized as well as with pasteurized or merely boiled milk. Less microbes were found with condensed milk, since there is less casein than in the ordinary cow's milk. Dreyfus adds that the tolerance for cow's milk was higher in the infants above the age of 6 months.

Passage of Amino-Acids and Sulphur from Effusions into Blood.—Loeper, Decourt and Lesure noted an exaggerated amino-acid content of the blood of patients with pleurisy, corresponding to that in the pleural effusion. This was observed also with sulphur.

Bile and the Bacteriophage.—Caublot's research was made on a patient with dysentery bacilli in pure culture in the urine. A bacteriophage strain had been adapted to the bacillus; and the patient had been successfully treated. Then the bacteriophage was treated with bile and kept in ampules. The dysentery recurred after a five month's improvement. The bacillus in the urine proved to be identical with that in the first attack. Cultures of the bacillus, exposed to the conserved bacteriophage, demonstrated that the lytic property of the latter had remained unchanged. Blood cultures in typhoid are said to be more rapidly positive in the presence of bile. It is evident, therefore, that bile promotes the growth of certain bacilli, but that this action is not due to any inhibition of the lytic power of the bacteriophage.

Nerve and Muscle Conduction and Chronaxia.—Lapicque and Veil state that the speed of nerve and muscle conduction was inversely proportional to the chronaxia in leeches and earth worms, in their research.

Contamination with Herpes Virus by Digestive Tract.—An emulsion of the brain from a rabbit that had died from herpetic encephalitis was given by the mouth to rabbits. Some of the animals ingested the emulsion alone, some after ingestion of bile. Death from herpetic encephalitis occurred in ten of eleven given the emulsion and bile; only in two of eleven given the emulsion alone. The grave infection in the bile-treated animals may be ascribed to the injury of the intestinal mucosa from it.

Availability of Rabbit Serums for Fixation Tests.—Pierret and Breton relate that while guinea-pig serums kept on ice lost 60 per cent of their complement fixation power in eight days, and 90 per cent in fifteen, rabbit serums kept the same way did not change at all. Their alexin value sometimes even increased by 1 or 2 per cent. This, as well as the dilution resistance of rabbit serum, demonstrates its value for complement fixation tests.

Serum Flocculation in Infections.—Flocculation occurred in all the serums from eight patients with cerebrospinal meningitis and from eighty-five with typhoid fever, in presence of a mixture of benzoin and an extract of the specific microbe. The serum from 295 syphilitics constantly showed flocculation in presence of a mixture of benzoin with the Bordet-Ruelens antigen. The flocculation does not destroy the agglutinating property of the serum in cerebrospinal meningitis and typhoid. These facts, Georgesco states, confirm Dujarric de la Rivière, Gallerand and Roux's findings.

Intradermal Test in Scarlet Fever.—Ciuca and Manoliu studied ten strains of hemolytic streptococci isolated from the blood or pus of scarlet fever patients. Filtrated cultures of the coccus were injected intradermally in ninety-four subjects at different stages of scarlet fever, in sixty-one with other infections, and in five healthy subjects. The intradermal reaction was positive in all, except only those in a state of anergy. They conclude from this that intradermal tests with hemolytic streptococci cannot be used for diagnostic purposes. They used partly the filtrate from cultures in dextrose bouillon, partly the same fluid diluted 1,000 times. The reactions with the latter were milder.

Bile Culture in Diagnosis of Typhoid.—Alexa and Munteanu aspirated the bile and used it for cultures, in thirty typhoid patients or convalescents. The results were positive in twenty, in ten during the disease, in eight convalescents, and in two clinically recovered. In the latter, the blood culture, and the serodiagnosis as well as examination of stools and urine were negative. Therefore the diagnostic use of the duodenal tube may be especially indicated in cases of typhoid carriers, in which other bacteriologic methods fail to reveal the bacillus.

Cholesteremia in the Insane.—Ornstein found an exaggerated amount of cholesterol in the blood of patients with chronic alcohol intoxication or mental confusion; less in senile dementia, pellagra, emotional psychoses and general paresis. The amount of cholesterol was reduced in the feebleminded, and in epilepsy and dementia praecox.

The p_H of the Blood in Rats with Sarcoma.—Laclau and Rabinovich's purpose was to determine the hydrogen ion concentration of the blood in rats with transplanted sarcoma. The tumor did not seem to influence the reaction of the blood.

The Calcium of the Blood and the Thyroid.—Castex and Schteingart did not observe any relations between the calcium of the blood and an increased or reduced functioning of the thyroid in their twenty-four cases. The disturbances from calcemia are probably due to changes induced in the vagosympathetic system.

Creatine of the Muscle and the Muscle Tonus.—Schwartz and Oschmann noted that the creatine content in striated muscles of frogs was neither decreased during atony nor increased during contraction.

Distribution of Anesthetics in the Blood.—Nicloux and Yovanovitch induced anesthesia of dogs with ethylene. There was evidence that from 70 to 80 per cent of the anesthetic was fixed in the blood corpuscles, and from 20 to 30 per cent in the plasma. This affinity for the blood corpuscles testifies that ethylene is a general anesthetic.

Susceptibility of Methemoglobin and Oxyhemoglobin to Reducing Agents.—Nicloux and Roche conclude that oxyhemogblobin is more susceptible to the reducing action of sodium hydrosulphite than methemoglobin.

The Glucose of the Urine.—Moeller recalls Lundsgaard and Holbøll's statement that the glucose in the blood of healthy persons is in the form of "neo-glucose", in grave diabetes it is in the form of alpha-beta glucose, in mild diabetes both glucoses are present. Analysis of the urine in three cases of grave diabetes and six of the mild form indicated that neoglucose and alpha-beta glucose are both eliminated by the kidneys.

Presence of Insulin Complement in Animal Muscle.—Lundsgaard and Holbøll found in the muscle of animals a substance or principle transforming alpha-beta glucose into neo-glucose, in the presence of insulin. They call it 'insulin complement."

*"Mental Prophylaxis" and Family Placement. A. Rodiet.—p. 114.

Hysteria and Epilepsy.—Rouquier and Vuillaume discuss the differential diagnosis of convulsions in hysteria and their association with true epilepsy.

Mental Hygiene and Prophylaxis.—Rodiet describes the workings of Toulouse's consulting service for the mentally sick and the service for securing a home in some family for convalescents from mental disease after dismissal from institutions. The majority of such patients are of country origin, and the family placement service was organized in a rural district (Lurcy). The patients agree to remain for three months at least, and they are provided with work on the farms and are encouraged to settle down permanently in the country. They are under supervision of some retired farmer who helps them to become self-supporting in time. Their board is paid by the state. If the local physician finds a tendency to a relapse or acute exacerbation, there are infirmaries and an asylum in the district, all linked in an extensive system for care of the insane, to relieve the institutions at Paris acutely overcrowded since the war. The family placement system was introduced in this district (Dun and Ainay) in 1893, and this extension of open door or free family placement completes the system of mental dispensaries in the city, providing a home for these uprooted beings. The address of the Société de patronage des aliénés guéris is 75, rue du Château-des-Rentiers, Paris.

Necrosis of Jaw from Radioactive Substances. A. Lacassagne.—p. 132.
*Roentgen Ray Treatment of Sterility. H. Caufman.—p. 135.

Roentgen-Ray Treatment of Surgical Tuberculosis.—Edling states that a cure was realized under roentgenotherapy in 73 per cent of 270 cases of enlarged glands, and 14.8 per cent were improved. Excellent results have been published by others with roentgen treatment of shoulder and elbow joints, but conditions are less favorable for it in the knee and ankle.

Roentgen Ray in Treatment of Sterility from Ovarian Disturbance.—Caufman treated a woman, aged 27, with irregular menstruation, amenorrhea alternating with metrorrhagia. The patient had been married for eighteen months, without conception. Roentgen rays were applied on two successive days, half a superficial skin dose for each ovary. The lumbosacral region was exposed as well as the abdomen, from navel to pubis. The treatment was followed by three normal menses, then pregnancy. The abnormal menstruation in this instance was evidently due to abnormal relations between the ovarian and uterine functioning. Here the roentgen ray may prove effectual, while it is contraindicated in primary amenorrhea or atrophy of the ovary, of infectious origin.

*Cerebrospinal Meningitis. J. Chalier and Schoen.—p. 99.
Fistulas After Appendectomy. R. Bonneau.—p. 101.
The Social Significance of Surgery. T. Tuffier.—p. 107.

Diagnosis of Thrombosis of Left Auricle.—Aubertin and Rimé describe the clinical syndrome which suggested obliteration of the left auricle in their two cases. It included cyanosis of the toes, fingers and nose, feeble pulse, very faint oscillometer record, and absence of the first heart sound, as well as dyspnea and arrhythmia. The dilatation and consecutive insufficiency of the left auricle had induced formation of blood clots which, gradually increasing, finally filled up almost the whole auricle, thus obstructing the mitral orifice. Notwithstanding the agonal clinical picture, the course was relatively slow, death occurring in one instance after nine days, in the other after five.

Cerebrospinal Meningitis with Meningeal Hemorrhage.—In Chalier and Schoen's two patients the cerebrospinal fluid looked like plain blood. These were cases of meningococcus epidemic cerebrospinal meningitis. Antiserum treatment, not begun until late, did not prevent the fatal outcome in a few weeks. Favorable results may be expected from early and intensive administration of antimeningococcus serum. Lumbar puncture with intraspinal injection of 30 cc. of the serum is indicated twice a day, combined with 30 cc. by the vein.

*Grafting in Knee Joint Disease. D. de Frenelle.—p. 117.
Anaphylaxis and Menstruation. H. Vignes.—p. 119.

Pathogenesis and Surgery of Angina Pectoris.—Daniélopolu ascribes the paroxysms of angina pectoris to a disproportion between the work of the heart and its blood supply. This may be induced by an effort as well as by lesions of the coronaries or aorta. Fatigue of the heart favors formation of toxins which stimulate the sensory fibers of the myocardium, inducing a pressor reflex of the heart and aorta. This reflex accelerates the heart contractions and raises the blood pressure, entailing a continuous increase of the toxins—a pressor reflex vicious circle—until the characteristic pain occurs. He advises surgical division of certain sensory fibers of the heart and aorta—the ones that conduct this reflex—while the accelerators and the stellate ganglion should be respected.

Bone Transplantation in Knee Joint Disease.—Dupuy de Frenelle uses a bone implant for treatment of knee joint disease in adolescents. Two grafts, taken from the tibia, are implanted laterally beneath the periosteum, after resection of *the diseased bone. He gives a detailed description of the* technic with nine illustrations.

*Intraspinal Anesthesia. T. Jonnesco.—p. 145.
The Duodenal Tube in Gastroduodenal Disease. Chabrol et al.—p. 147.

Technic for Intraspinal Generalized Anesthesia.—Jonnesco has used exclusively intraspinal anesthesia in 6,200 operations within the last eighteen years. He states that there was no fatal outcome or any untoward complications. He ascribes these excellent results to the technic employed. Stovaine, mixed with caffeine and sodium benzoate, is injected with a very thin needle. He injects in a cervicodorsal puncture, for a high operation, from 0.03 to 0.06 Gm. of stovaine, 0.50 Gm. of caffeine and from 0.65 to 0.70 Gm. of sodium benzoate, in 2 cc. of sterilized water. In dorsolumbar puncture for abdominal operations, he injects in 1 cc. of water from 0.04 to 0.08 Gm. of stovaine, 0.20 Gm. of caffeine, and 0.30 Gm. of sodium benzoate. In operations on the thorax, the dose is fractioned and injected with two punctures at the high and the middle points. In gynecologic operations, two injections, the dorsolumbar and the low lumbar are indicated, half of the solution being injected at each puncture. In cases in which postoperative retention of the urine is feared, caffeine may be replaced by strychnine. The dose of stovaine should be reduced in patients with unsatisfactory general condition.

*Classification of Meningococci. E. M. Claveaux.—p. 741.
*Visualization of the Gallbladder. P. A. Barcia et al.—p. 763.
Work in Treatment of Mental Disease. Garmendia and Darder.—p. 783.
Experimental Study of Chronic Traumatism. C. Stajano.—p. 792.

Classification of Meningococci of South America.—Of the thirty-five strains of meningococci cultivated from the cerebrospinal fluid, fifteen were from Montevideo, ten from Brazil and nine from Buenos Aires. The type most frequently found was type 3 of the American classification, then type 1. Of the French classification, type D predominated. The various tests and passages through animals confirmed that all the types closely resemble each other; they differ mainly in the agglutination property, and this is not vital. All show a mixture of different antigens, consequently Claveaux advocates a polyvalent antiserum, urging that the antiserums should be made from the largest possible number of autochthonous strains.

Visualization of the Gallbladder.—Barcia, Menéndez and Leborgne *give forty-two fine roentgenograms, mostly serial,* after intravenous or oral administration of tetraiodophenolphthalein, and expatiate on the instructive findings as to conditions in the upper right quadrant of the abdomen.

*Convulsions in Cyclic Vomiting. E. Portú Pereyra.—p. 1174.
Tetanoid-Comatose Form of Acetonemic Vomiting. V. Zerbino.—p. 1177.

Pneumococcus Infection of the New-Born.—Garrahan and Bettinotti discuss an epidemic of pneumococcus infection in six new-born infants in a period of three months at the Rivadavia maternity. Only one survived; the five others succumbed to meningitis or pneumonia in a few days. In one case a forceps injury of the eyeball was the portal of entry of the infection, the pneumococcus being cultivated from the conjunctiva. One of the mothers had influenza.

Congenital Heart Defect in an Infant of Mongolian Aspect.—Recurring attacks of cyanosis testified to some abnormal communication between the ventricles in the young infant. The attacks seem to be decreasing in frequency.

Epidemic Poliomyelitis and Chorea.—Three cases of acute chorea developed in children of about 7 in the course of a prevailing epidemic of acute anterior poliomyelitis. There was no history of febrile rheumatism, syphilis, congenital or acquired, nor degeneracy, and nothing to suggest epidemic encephalitis. By exclusion, Estapé assumes that the chorea in these cases was a manifestation of the epidemic poliomyelitis virus. He offers this as a "working hypothesis or, rather, working prosthesis."

Acute Fatal Encephalitis in Whooping Cough.—Bonaba and Leunda encountered two cases of this kind within three days. The patients were children between 2 and 3. In the course of whooping cough without complications, they suddenly developed convulsions which continued without intermission for three and eight hours until death brought relief. Influenza and epidemic poliomyelitis were prevailing at the time. Necropsy in one case revealed acute congestive encephalitis.

Cyclic Vomiting.—Portú Pereyra relates the case of a boy, aged 5, who suddenly developed intense convulsions, followed by profound coma, after eating a little fruit. Vomiting persisted for forty-eight hours. He had had two similar attacks before but none so serious. Acetone and diacetic acid were found in the urine but not in the spinal puncture fluid. He was given nothing but water and a 3 per cent solution of bicarbonate, and by the fourth day had recovered. In Mackenna's forty-five observations of acidosis in children, there was no instance of convulsions, but Zerbino reports a case of a grave tetanoid-comatose acetonemia syndrome in a child of 3. There was no vomiting and no urine, and the child died the next day.

Weight Curves of Infants.—Stoeltzner points out that the weight of infants does not increase regularly, which is especially evident, when recorded daily. A decrease of 5 Gm. is frequent and is not abnormal, if the increase averages 25 Gm. The change of weight is only the result of the two divergent tendencies. Consequently the actual gain in weight is always smaller than the tendency to gain. The latter, as well as the tendency to lose, may be estimated better by taking the average of the daily (instead of weekly) gain or loss. Both tendencies are independent. Undernourishment inhibits usually only the gaining tendency, if it does not last long. In nutritional disturbances of a moderate degree, both tendencies are exaggerated at first. The balance is higher than normal. Similar interesting data might be obtained by analysis of the weight curve in other conditions.

Spider-Web Clots in Nontuberculous Meningitis.—Post concludes that spider-web clots occur not infrequently with epidemic and sometimes even with a serous meningitis. They form more rapidly (in two hours) and are thicker—because of the adsorption of leukocytes—than in tuberculous meningitis.

Treatment of Jaundice of the New-Born.—Slobozianu gave daily 0.1-0.2 Gm. of cinchophen, in suppositories, in jaundice of the new-born. The duration of the jaundice was shorter than in untreated infants.

Bismuth and Blood Changes. Andreas Tüdös and P. v. Kiss.—p. 219.
*Chvostek's Phenomenon. J. Stargardter.—p. 225.

Goat's Milk Anemia.—Glanzmann observed goat milk anemia only in neighborhoods where the goats were kept in dark stables and did not get good fresh fodder. The anemia resembled the pernicious type (high color index, low percentage of monocytes, urobilinuria). The milk inducing anemia had usually a strong "buck" odor. He is inclined to incriminate the fats as the cause of the anemia. The vitamin A content of goat's milk was lower than in cow's milk, and the vitamin C content was very low. This accounts for the frequent dystrophy in such infants. It was easier to obtain grave anemia in guinea-pigs by feeding them cow's milk than with goat's milk, but the regenerative changes were strong with the cow's milk, and seemed to be inhibited by the goat's milk.

Muscular Exercise and Hardness.—Opitz and Isbert found in children an increase of about 14 per cent in the hardness of muscles and persisting for ten or fifteen minutes after muscular exercise leading to fatigue. Systematic daily exercise and sanatorium treatment harden the muscles.

Whooping Cough.—Szontagh has never seen a case of infection of other children by a child with whooping cough. He regards it as a symptom of the neuro-arthritic diathesis—especially in the convulsive stage, which, he thinks, is due to the action of some toxin on the cough center. Epidemics of whooping cough alternate with those of measles, and he can find no satisfactory explanation for this. He believes that the activating condition is a contagium volatile.

Irradiated Milk in Rickets.—György treated children with milk and gruels which had been irradiated with artificial sunlight for half an hour to an hour. The milk acquires a taste resembling that of cod liver oil. The symptoms of rickets and tetany disappeared in sixteen of the eighteen children fed with this "jecorized" milk.

Chvostek's Phenomenon.—Stargardter attributes the Chvostek facial phenomenon to spasm of the blood vessels of the nerves. Friction or warming of the cheek arrests the spasm of the vessels as well as the facial phenomenon. The spasm plays also a rôle in tetany—supplementary to the irritability of the nerves due to lowering of the calcium ions of the blood.

Protein Content of Puncture Fluids. J. Kleeberg.—p. 47.

Field of Vision of Single Eye.—Kleist has collected evidence indicating that the differentiation of a layer of the cortical center of vision into two depends on the development of a field of vision common to both eyes.

Insulin Fractioning in Children.—Priesel and Wagner recommend in diabetic children daily two doses of insulin, twelve hours apart. The first is given at the latest at 7 or 8 a. m., and should be larger than the second. The same amount of carbohydrates given in the morning causes a higher glycemia than at noon.

Roentgen-Ray Treatment of Postoperative Pneumonia.—Fried irradiated forty patients with postoperative pneumonia. Only one of them died. He also had fair results in nine cases of pneumonia of other origin.

General Paresis and Mesaortitis.—Coenen found syphilitic mesaortitis in 22 per cent of the 191 general paresis necropsies made in 1908-1914. Among 147 cases from 1915-1925, mesaortitis was present in 42.9 per cent. He discusses the relation to treatment, but admits that his material is insufficient to decide the question.

Suicides After War.—Freudenberg publishes statistics on suicides in Germany between 1911 and 1923. The frequency of suicides in men declined about one third during the war. The figures for women show a slow and steady increase. Age and occupation give other interesting indications on the causes of suicides.

*Mineral and Especially Iron Metabolism. E. Oppenheimer.—p. 76.
Capillary Tonometer. E. Rajka.—p. 87.

Scurvy and Chronic Tuberculosis.—Heymann found no influence of avitaminosis on the course of tuberculosis in guinea-pigs, but the scurvy was accelerated by the tuberculosis. One of the sources of experimental errors, he found, is the fact that some guinea-pigs do not learn to drink water, and die on the dry diet.

Iodine Reaction of Blood Platelets.—Rokay does not consider Stahl's observations on iodophilic clumps in the platelets and megakaryocytes suitable for deciding on the origin of the blood platelets.

Bacteriology of Material Contaminated by Proteus.—Schuback prepares an agglutinating serum, with various strains of proteus bacilli and adds 0.2-0.3 cc. of it to 10 cc. of agar. The serum inhibits the spreading of the proteus all over the plate.

Wassermann Reaction Induced by Injection of Lipoids and Serum.—Brandt, Guth and Müller injected animals with hog serum alone or mixed with lipoids. The serum from these animals reacted only weakly with those antigens which proved best in the Wassermann reaction. The reaction was never stronger than with simple lipoid antigens.

Prevention of Congenital Syphilis.—Boas reviews all the means for prevention of congenital syphilis. Besides other measures, arsphenamine treatment of the mother before and during the pregnancy gave the best results (six healthy children out of seven). Mercury administered during the pregnancy is much less efficient: Of the children from twenty-six mothers who had received arsphenamine before and mercury during the pregnancy, seven of the twenty-six were syphilitic. Only one healthy child was found among 158 born from untreated mothers.

Mineral and Especially Iron Metabolism.—Oppenheimer emphasizes the importance of Baudisch and Web's experiments on the "X factor" of fresh mineral waters responsible for their catalytic and oxidizing action. Very labile compounds of iron—investigated among other methods with roentgen rays—were discovered. They may represent the original form which developed into blood.

*Cardiac Asthma. S. Wassermann.—p. 1.

New Clinical Points of View on Cardiac Asthma.—Wassermann devotes 168 pages to discussion of the pathogenesis and clinical aspects of cardiac asthma. The typical attacks occur *with insufficiency of the left ventricle,* and have primarily nothing to do with a retrograde stasis: The attack is a reaction of the central nervous system (especially the medulla) to anoxemia. Insufficiency of the aortic valves and infarctions in the left ventricle are the main causes. Morphine, oxygen and nitrites are indicated. The second type of cardiac asthma—due to stasis in the lungs—is characterized by cyanosis, and does not cause an acute increase in blood pressure. Mitral disease is the usual cause. Venesection, digitalis, caffeine, oxygen and, sometimes, small doses of morphine are indicated, although of little help.

*Temperature and Allergy in Menstruation. G. Gáli.—p. 212.
Meinicke's Test in Sanatoriums. O. Eicke.—p. 218.

Tuberculosis of the Heart.—Stefko found tuberculosis in the heart in 80 per cent of his necropsies of the persons who had died from tuberculosis. He attributes this to the change of the condition of the heart due to the Russian famine. The reaction consists of an epitheloid infiltration, originating in the endothelium of the capillaries, and a subsequent phagocytic action of the newly formed cells, which, however, only removes the waste products. The cellular infiltration in tuberculosis of the heart in cattle is of the fibroblastic type.

***Temperature and Allergy in Menstruation.**—Gáli finds that* menstruation does not influence the temperature, nor the allergic manifestations of tuberculous women.

*Calcium Treatment in Tuberculosis. J Pinkhof.—p. 230.
Ethyl Chloride Anesthesia. W. C. Meiss.—p. 235.
*Acute Salpingitis or Appendicitis? B. S. ten Berge.—p. 243.
*Jaundice in the New-Born. P. H. Kramer.—p. 249.

Calcium in Treatment of Pulmonary Tuberculosis.—Pinkhof has been favorably impressed with the effects of intravenous injection of 5 cc. of a 10 per cent solution of calcium chloride in treatment of febrile cases of pulmonary tuberculosis rebellious to other measures, but with the organism still capable of responding to stimuli. The injections were made three times a week, in three series of twenty injections, and he never witnessed any untoward by-effects in the 100 sanatorium cases (three years; 3,000 injections). In forty cases they were given merely for the subjective influence, as the condition was hopeless, but he was surprised at the unmistakable benefit observed in a few in this group. In forty of the sixty others the improvement was pronounced. The calcium seems to reenforce the general resisting powers, accomplishing a general improvement and thus indirectly influencing the fever. The temperature returned to normal in the first series in twelve patients; the sputum rapidly became more fluid and less in amount, and the physical findings soon changed for the better. No effect from the calcium treatment was apparent in ten cases and ten others failed to complete the course.

Acute Salpingitis Versus Appendicitis.—Ten Berge analyzes twenty-four cases in which the diagnosis wavered between appendicitis and acute salpingitis. His experience shows the necessity for treatment as if for appendicitis in case of doubt; only three in the group proved to have salpingitis instead, and in all these the appendix was more or less involved. In the twenty-one pure appendicitis cases, leukorrhea was common and there was urethritis in three and menorrhagia in eight, and in seven there was pain on pressure to the left, above the symphysis. Three complained of intense pain during vaginal examination. Examination through the vagina and rectum is most instructive in exacerbations of an old process; in a recent infectious process, the adnexa are not much enlarged.

Jaundice in the New-Born.—Kramer found bilirubin in the blood of the umbilical cord in amounts ranging from 1:28,000 to 1:140,000; the average 1:46,000. The van den Bergh indirect reaction was pronounced, but the direct reaction was never observed in the 100 new-born tested nor in a number of other infants a few days old. All with more than 1:36,000 bilirubin presented jaundice, and none of those with 1:70,000 or below. His findings confirm that mechanical jaundice does not occur in icterus neonatorum. There seems to be a progressively increasing bilirubinemia in all mammals for a few days after birth. Destruction of surplus erythrocytes (fetal and maternal) might account for this. He thinks that it represents a reserve supply, like the large iron reserve with which the child is born.

Delivery of Child with Hydrocephalus in Breech Presentation. Van den Berg.—p. 446.
The Conference of the International Public Health Bureau at Paris, Oct. 21, 1926. N. M. J. Jitta.—p. 466.

Pathologic Glia and the Conception of the Cell.—Bok insists that the becoming visible of the glia protoplasm in the Nissl preparation is due to a chemical change in the protoplasm and a slight swelling, a physical change, both of which begin at the nucleus and spread thence, growing progressively fainter. The cells cannot be regarded as individual building stones. The alleged cell is merely the sphere of influence of a nucleus lying in a field of protoplasm, which connects uninterruptedly with the protoplasm of the adjacent so-called cells. The article is illustrated; it issues from the university laboratory at Amsterdam in charge of Bouman. His arguments sustain the syncytium theory of the cells.

General Intoxication from Mercurial Ointment.—Hamburger had ordered gray ointment to destroy crab lice in the pubic hair, but the man applied it as a regular vigorous inunction five times within sixty hours. He then developed symptoms suggesting intestinal invagination or dysentery until the mercurial poisoning was recognized.

Diathermy in Treatment of Gonorrhea.—Van Putte relates that he cured both clinically and bacteriologically ten women with old and rebellious gonorrhea by means of five hours of diathermy in a single day.

Cure of Purpura by Splenectomy.—The special form of grave purpura due to essential thrombopenia was cured at once by the splenectomy in the case described. The bleeding time was forty minutes and there were scarcely any thrombocytes to be discovered before the splenectomy. It was followed by a drop to fourteen minutes at once while the monocytes ran up from zero to a million in about two weeks. The discovery of the thrombopenia in the blood gave the clue for successful operative treatment. The hemoglobin percentage dropped to 50 but gradually rose to 80 in three months.

69: 29-48 (Jan. 14) 1926

*The Thalamus Syndromes. G. Roussy.—p. 29.

Function of the Thalamus Opticus and the Thalamic Syndromes.—The clinical picture described by Dejerine and Roussy in 1906 as the thalamus syndrome is characterized by the dissociation of the motor and the sensory phenomena; the motor symptoms may subside but the sensory are permanent. Roussy here reviews the other syndromes which may be induced by lesions in or in the vicinity of the thalamus. He has encountered cases confirmed by necropsy in which there was no spontaneous pain, while in other cases emotions, even music, induced pain in the tributary region. He accepts Lhermitte's recent hypothesis that the thalamus is an analyzing organ, a selecting filter for the sensory streams, all of which pass through it. When any essential portion of this analyzing organ is destroyed, the sensory impulses pass onward to the cortex instead of being selectively arrested by the thalamus, as in normal conditions. The hypothalamus syndrome is distinguished by the lack of pains and the presence of cerebellar disturbances. A circumscribed lesion in the corpus striatum causes hypertonia or hypotonia, muscular rigidity or muscular jerking, according to the portion involved. The physiology and pathology of the thalamostriatal centers are proving so important in respect to sensory impulses of all kinds and control of the grouping and combinations of involuntary movements, that we must regard the central ganglion system, he says, as something more than a mere humble servant of the thinking apparatus. This article formed the Rask-Orsted fund lecture delivered by Roussy at Copenhagen recently.

Ugeskrift for Læger, Copenhagen

87: 1193-1202 (Dec. 31) 1925

*Brain Tumor. H. Jessen.—p. 1193.
*Vaccine Therapy for Bronchitis with Asthma. G. Hagens.—p. 1195.
Separate Ampules for the Solution of Procaine and of Epinephrine and Mixture in the Syringe for Local Anesthesia. Sennels.—p. 1196.
Expenditures of Six Physicians' Families in 1922. P. Heiberg.—p. 1197.

Successful Operation for Brain Tumor.—Jessen's patient was a woman, aged 50, who four years before had noticed that she could not use her left leg in bicycling. Other symptoms gradually developed, suggesting a tumor in the motor region, left cerebral hemiplegia, complete for the leg, partial for the arm, bilateral choked disk and impairment of vision, but no jacksonian symptoms. The tumor was found in the right fissure of Rolando, adherent to the dura, but it was easily shelled out from the brain tissue with the finger. It was the size of a mandarin orange and soft, of the endothelioma or meningeoma type. The dura and the skin were sutured, leaving only a small cigaret drain, and no attempt at radiotherapy was made. The outcome surpassed all expectations. Vision is now practically normal in one eye and fairly good in the other, and the hemiplegia has entirely subsided, leaving only a little weakness and persisting impairment of the sense of position in the foot.

Chronic Bronchitis with Asthmatic Attacks.—The middle aged woman had been having chronic bronchitis for nearly five years, with attacks of asthma, the whole so severe that she was confined to bed most of the time. Two intercurrent attacks of influenza had been followed by such marked improvement for a time that Hagens tried autogenous mixed vaccines, aiming to induce fever with them. Benefit promptly followed, the same as after the febrile influenza, and has persisted for three months to date.

88: 79-102 (Jan. 28) 1926

*Pernicious Anemia. H. C. Gram.—p. 79.
*Protein Therapy for Erysipelas. A. Jensen.—p. 87.

Etiology and Pathogenesis of Pernicious Anemia.—Gram presents an array of testimony to sustain his assumption that pernicious anemia is a chronically intermittent intoxication with toxic substances which act on the blood cells in the circulation and in the bone marrow, thus inducing hemolysis and a pathologic regeneration, with lack of myelogenous leukocytes and blood platelets. The toxic substance acts also on the stomach and on the buccal mucosa, inducing glossitis with irritation of the tip of the tongue and atrophy of the papillae, and gastritis with achylia. These changes may occur long before the pernicious anemia becomes manifest. The toxic substance sometimes induces a disseminated myelitis with symptoms in the form of paresthesias and anesthesia. The source of the toxic substance seems to be in the small intestine, and to proceed from the bacteria or from the bothriocephalus therein contained. The abnormal or excessive flora in the small intestine and an increased permeability for the toxin formed or the failure of the toxin-resisting mechanism are essential factors, and these may have a familial or hereditary character. Naturally, any stricture or other lesion impeding bowel function will tend to render the bacterial flora more abnormal and thus start a vicious circle. Any fluctuation in any of the factors may entail a remission.

Protein Therapy of Erysipelas.—In the four cases of erysipelas of the face described, intramuscular injection of 5-10 cc. of cow's milk the second, third or fourth day seemed to arrest the process at once, and a second injection completed the cure. The skin was natural again in six days in one case and had scabbed over in four days in another case.

INDIVIDUAL VERSUS GROUP RESPONSIBILITY FOR THE CARE OF THE HOSPITAL PATIENT*

HENRY A. CHRISTIAN, M.D.
BOSTON

Changing conditions and methods of medical work may necessitate readjustments of the relationship that exists between the physician or surgeon and his patient. Group methods have entered medical practice. Complexity in the technic used in diagnosis and treatment has been one of the causes of the development of these group methods. It is hardly possible for the single individual any longer to do with his own hands all the things needed for the diagnosis and treatment of the individual patient with anything other than a very simple malady, and it is increasingly difficult for him to possess the desirable range of knowledge of medicine to handle alone complicated cases. This is recognized in all varieties of practice by the calling in of consultants, by the utilization of such special methods of diagnosis as the roentgen ray, the determination of a Wassermann reaction and many others, of which these two may serve merely as examples, and by the employment of such special therapeutic methods as the intraspinal injection of serum, transfusion of blood, applications of special forms of heat and radiant energy, and the surgical removal of diseased organs and neoplasms, these few being cited as examples of what might be multiplied almost indefinitely. All of this involves work on the patient by more than one individual and so constitutes group practice. The one constant factor in all these changing conditions is the patient and his need for help. On the one hand, in most instances, there is the group in some form, and, on the other, the patient.

How are these two factors in medical work, the group and the patient, going to be brought together in the most advantageous way? It is perfectly evident that the patient needs to receive advice and direction based on the work of the group, if he is handled by a group. There has to be a responsibility somewhere for getting understood by the patient what he should do in order to improve his physical condition, or, this being impossible, how best to adapt himself to his disability in order to minimize its effect and retard its progression. This very largely resolves itself into some individual of the group assuming a responsible advisory relationship to the patient, for it seems, to say the least, a waste of energy for the group as a whole to assume this responsibility, even were it a feasible arrangement. The more personal and intimate this individual contact becomes, the greater the benefit that the patient is to receive, for it is quite impossible to divorce the influence of the personality of the physician on the personality of the patient from the practice of medicine. If it is done, the therapeutic measures advised for the patient at once lose in their potency. What has been said above applies equally to the patient in and out of the hospital. In the hospital and the diagnostic clinic, group work is apt to be more highly organized than elsewhere, often the reason for the patient's going to a hospital or a clinic is to obtain the benefit of examination by a group. This is particularly true of the hospital or clinic that is operated in large measure as a diagnostic clinic. Here it is that the lack of an individual responsibility to the patient is most apt to be found, whether the problem concerns diagnosis or treatment.

Judging by the expressions of opinion that I have heard from patients about the group method of practice, its greatest defect lies in the feeling of the patient that he has missed a personal interest in himself, and that he suspects that he has not quite understood the results of his examination and has but vague ideas of what it is intended that he should do, largely because no single individual of the group has spent sufficient time considering him and talking to him as a whole organism needing new adjustments. As I myself have subsequently seen patients who have gone to a group for diagnosis, these misgivings of the patient often seem justified. The mistakes that are made appear to have originated usually because the most matured clinician of the group has failed to observe sufficiently long and sufficiently frequently the patient as a human personality in relation to the various diagnostic data accumulated in the group study, and because advice to the patient is given in too hurried a way without opportunity for the patient to ask many questions which he needs to have answered.

To me, group responsibility to the patient seems well nigh an unworkable relationship; individual responsibility is necessary. How is this to be brought about for the hospital patient? It seems to me that some one member of the hospital staff has to bear a responsible interpreting and directing relationship to the patient at every stage of his progress through the hospital; it may not be essential for the same individual to act continuously in this relationship to the patient, though it seems desirable that he should. A good deal will depend on the organization of the hospital and on what has to be done to the patient.

Hospitals, as organized at present, may be divided into several groups: (*a*) hospitals with separately organized services, medical, surgical, etc.; (*b*) hospitals that are primarily for one type of patient, surgical, medical, obstetric, nose and throat, etc.; (*c*) hospitals primarily organized as a diagnostic service through which patients are selected for special forms of therapeutics.

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 18, 1926.

In the hospital with separately organized services, one of two plans may be followed: Either each service is a complete organization capable of handling practically all types of patients admitted to it with an occasional request for consultative help from the other services, or it is less independently organized and the request for aid from the other services is generally a part of the management of the patient. It would seem that in either plan a responsible member of the visiting staff should hold a direct advisory relationship to every patient and assume all professional responsibility for that patient, including the responsibility for arranging for the patient to be seen in consultation by whoever can help in arriving at a satisfactory diagnosis and planning an adequate form of treatment. Of this type are the great bulk of the larger hospitals of the land, and in them, as a rule, patients receive very satisfactory care, including such advice from consultants as is needed, and are brought into a responsible relationship to some member of the staff.

The second type of hospital might be termed the special hospital. Usually it is a smaller institution. In smaller towns the hospital is apt to be of this type; particularly is it a surgical hospital. In these hospitals, patients are usually under the care of but one man, and often the hospital differs from the patient's home only in having an operating room attached to it. Probably there are more of this type of hospital than any other in the land. Here there is no question as to who is responsible; necessarily it is individual responsibility. The question is, Does the patient in this type of hospital get sufficient examination and consideration by those with special training and capability over and above what the medical or surgical man in responsible charge can give? That this has to be answered in the negative in many instances all would, I believe, agree.

The third type, the hospital organized primarily as a diagnostic clinic, is on the whole new and not numerous. To many it would seem that this type of organization is likely to be brought into the large majority of our hospitals in the future. In it the problem is largely that of determining who, of a professionally completely adequate staff, shall bear the relationship of individual responsibility to the patient and of providing opportunity and time for this relationship satisfactorily to be carried out. In this type of hospital the organization is primarily intended to provide for each patient the application of all needed diagnostic methods, and the only danger lies in accepting the form of applying many methods as necessarily involving a thorough examination of the patient, and in not integrating the data obtained into an intelligent diagnosis, prognosis and advice as to treatment. There is a danger of allowing the doing of numerous tests, some or many probably done by none too dependable technicians, to take the place of a thorough examination by an experienced clinician. It is well to remember that no multiplication of tests can be regarded as anything other than supplementary to the personal study by such an experienced clinician, and that no experienced clinician can make an adequate study of the patient in a very brief period of time. It would seem necessary, in order that such a hospital function for the best interests of the patient, to have a responsible relationship established between one of the more mature clinicians of the staff and the patient. In such a hospital the surgeon is part of the diagnostic team contributing to diagnosis what his special training fits him for. In addition, he is one of the therapists of the hospital, carrying out in a responsible way the surgical therapeutics advised for the individual patient.

From what has been said, it would seem that in the first and third types of hospitals the patient generally receives adequate service, and that this service is likely to improve under existing plans of organization. Furthermore, generally in the first type there exists a satisfactory personal responsibility to the patients and in the third type the need of such a relationship is recognized, even though it is not actually provided in every instance. The real improvement in this type of hospital must come not from rules of procedure but from securing for the staff men with better professional training. This applies to internists fully as much as to surgeons. For the latter, the ability to operate well should, in my judgment, be regarded as inadequate unless there goes with it the capability to diagnose. As has been so often said, the decision as when to operate and what operation to undertake requires fully as much skill as does the actual operation technic.

It is in the second type of hospital that inadequate service is apt to be rendered the patient; here the relationship of individual responsibility exists but the patient often lacks intelligent use of the technic of special examinations, etc.

Dr. Goldwater tells me that lately several hospitals have been asked to adopt a rule providing that no major operation is to be performed without previous consultation with an internist. I suspect that this has originated from finding that the defects in the second type of hospital, such as I have pointed out, exist and need a remedy. The query is whether the proposed remedy is likely to be effective. Of this I have grave doubts. The requirement of a consultation with an internist before a major operation seems to me illogical. If it implies an inability of the surgeon to make a diagnosis, as it apparently does, it seems to me that the remedy lies in either not allowing such a surgeon to operate at all or in organizing a diagnostic group for which that surgeon merely carries out one form of treatment; namely, surgery. I would question the desirability of the latter arrangement, which would reduce surgery to a merely mechanical form of therapeutics. Would not this type of surgeon, already judged by his hospital to be untrained or unsuited for diagnostic work, be a poor operator because lacking in those qualities of the brain needed of the surgeon fully as well as dexterity of the hand? I think so. Again, in a hospital with a surgeon of such a type one might query whether the consultation of an internist might not be merely perfunctory to fulfil the requirement or unsatisfactory because of lack of training and ability in the internist. Then, too, would it not divide responsibility in an undesirable way? It would seem that it was unfair to expect the internist to assume responsibility for the work of the surgeon, yet, in final analysis, that would seem to be what the rule might be requiring of him.

If the hospital is organized as a diagnostic group, then diagnosis will have been made by the group and treatment should be determined by some one responsible member, presumably in case of surgical treatment by the surgeon member of the diagnostic group. In the large general hospital, especially the teaching hospital, I believe the surgeon would be entirely capable of and should determine when consultation is or is not desirable, and so proceed to operate with or without it as he determined. Not possessing such capability, he certainly should not hold the position. In the smaller, special type of hospital a satisfactory solution of the problem is difficult. The solution, it seems to me, should be along the lines of preventing the work of the surgeon of doubtful ability rather than of trying to decrease the damage he may do by requiring of him a consultation with an internist before undertaking a major operation. Better surgeons and better internists are needed rather than more rules for their conduct in relation to patients.

In any type of hospit [illegible] onvinced that there should be an [illegible] for the care of the patient, not a group responsibility. Numerous ways of selecting the individual for this relation to the patient could be thought of, any one of which would work with complete satisfaction, provided this responsibility is recognized by both staff member and patient and the staff member, selected for the responsibility, is a broadly trained, competent clinician. The method actually adopted needs to fit the varying circumstances of difference in organization and difference in the personality of the personnel. Rules or precedents suited to one institution might easily prove completely ineffective at another place. Consequently it would be unwise for any central body to attempt to draft rules to be applied generally. It is sufficient to insist on an actual individual responsibility to the patient in his professional care.

INDIVIDUAL VERSUS GROUP RESPONSIBILITY FOR THE CARE OF THE HOSPITAL PATIENT *

HUGH AUCHINCLOSS, M.D.
NEW YORK

Responsibility means the state of being responsible. Our dictionaries define being responsible as: (1) being answerable legally or morally for discharge of a duty, trust or debt; (2) being able to meet obligations, or (3) having a perception of the distinctions between right and wrong.

You may profitably discuss some of the myriad ways care of hospital patients demands responsibility. With your leave, I shall not. We all know they exist and that they have to be met by group or individual. Whether they can be best dealt with by the individual or by the group is our concern.

The precise meaning of our subject is susceptible of varied interpretation, according to the experiences of doctors in their several communities. My discussion must be confined to principles seemingly pertinent, gained in limited personal experience.

A hospital patient first encounters the admitting mechanism. In a sense, this is a group. If it is an emergency case, the patient is at once seen by a physician. His pedigree, civil status, and the estimation as to what sort of a case it is awaits the physician's decision. Soon, however, whether it is an emergency case or not, the pedigree is written by a lay official, a professional record of his illness is begun, and he becomes an object of concern to all, or any, branches of the hospital that may have a contribution to make on his condition. Who, then, shall determine the course of procedure; one physician, in conjunction with any other physicians he may choose to summon, or a group of physicians, who, through their various methods of approach, may be expected to overlook less with their multiple eyes than the individual, with his two?

Is it better to be taken care of by a group of specialists in the hope that the especial lesions one has will more surely come to the attention of the special physicians trained in these lesions, or is it still possible for one physician to determine in a careful history and physical examination what the troubles are and call for special help when needed?

Probably very few in this audience or anywhere would be willing to advocate a too rigid maintenance of either method. Almost surely in every hospital where so-called group responsibility may be supposed to dominate, the individual plays the major part in the individual case quite as much as the individual physician summons aid from his associates where the other scheme obtains.

As inbreeding accentuates good or bad inherent factors, so may an artificial and exclusive selection of one method or the other resemble the little girl with a curl in the middle of her forehead: when it is good, it is very, very good, but when it is bad, it's horrid. It is surely not so much the mechanism by which our patients are cared for as it is the quality of medical care with which they are surrounded

Probably no one here but has had patients who have come from some institution where every conceivable medical analysis has been carried out without clearing a problem requiring only time, ordinary knowledge and common sense to solve Just as true is it that institutes and groups may thrive on the errors of omission and commission of the individual

The recognition of the essential features in a case, that is to say, the art of extracting the essence in medicine, may be done by a group or an individual, if quality is there. Is quality, then, fostered best by the group or by the individual? But is not the group made up of individuals? It certainly is; and where mass production is required, many of the great army of workers may be artists at heart. But, in general, the artist works alone.

Our hospitals, however, are not places where time hangs heavy on one's hands. The pressure is great and patients are plentiful. Work comparable to mass production must be done, though the individual physician balks at the idea that he be restricted to handling but one part in the machine. It is true that a taste and schooling in a special field influences his activities. His main attention, however, should be constantly riveted on the patient as a whole.

Perhaps the chief risk to which a so-called group system exposes itself is a failure to place responsibility on anything that is tangible. Groups melt like a mirage if things go wrong, and a patient with a wholly justifiable complaint may end up begging somebody's pardon for satisfaction.

"From pillar to post," or, in cruder vernacular, "passing the buck," has a meaning requiring no explanation. It is associated with the group plan more than when responsibility is shouldered by the individual. This shelving of responsibility is one of the worst features in hospitals. It is bad for the patient, worse for the nurse, inexcusable for the physician, and a wretched quality of medicine. "The quality of" medicine "is not strained; . . . it is twice bless'd; it blesseth him that gives and him that takes." No man, of course, should attempt medicine unless he is willing to have troubles brought to him, be bothered, and hear tales of woe, for every

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb 18, 1926.

patient has one. I can scarcely believe that the same sense of responsibility can be felt by the individual physician in a group system, when a patient reaches his domain in making his medical journey, as is undertaken when a patient is assigned to some physician who, with the joint action of such associates as he may choose, undertakes to find out what is wrong with the patient and set him straight.

Theoretically, one can figure out that no great difference in assuming responsibility ought to exist between the two methods. But human nature is fallible, and the more tangible responsibility is, the more likely it will be lived up to.

To have group facilities available with an individual assigned the responsibility of the patient as a whole would seem a natural sequence to this line of thought. Indeed, it is pretty much what is being done and is likely to be done for some time to come. Our hospitals in their outpatient departments, in their varied laboratories and services and their consultants, provide group facilities. The mechanism is there. Assign the patient to a physician, let him be transferred, if need be, to another, but let him feel that some one physician is responsible for him. One cannot stop the play of forces in evolution. Our arguments pro and contra will not bring the group system nor retain individual responsibility. We may forearm, however, by forewarning of the dangers of intangible responsibility, and hurry the possession of valuable factors, such as joint thinking and action, by stressing their advantages.

Just as Drs. Sprague and Minchin are compared in Middlemarch: "In short, he had weight and might be expected to grapple with a disease and throw it; while Dr. Minchin might be better able to detect it lurking and circumvent it," our methods as physicians vary and require joint thinking and endeavor. On nearing the woods, however, patients soon look for the trees, and in uncanny fashion come to know which they are, select their favorite oak, dickory, maple or chestnut, seek shelter during storm, shade during heat, and camp 'neath his branches till sundown. Let him shirk this responsibility, and he is no physician.

The effectiveness of a group of physicians in a hospital depends on their degree of intellectual sympathy. Whether they agree, or agree to disagree, do they talk the same language? "It is not enough to have earned our livelihood. Either the learning itself should have been serviceable to mankind, or something else must follow."

Our hospitals have the mechanism for using groups or individuals. Have they the men? If they have, the mechanism matters less than we think.

"'What d'ye think about it?' asked Mr. Hennessey.

"'I think,' said Mr. Dooley, 'that if th' Christyan scientists had some science an' th' doctors more Christyanity, it wudden't make anny diff'rence which ye called in—if ye had a good nurse.'"

Though my talk may seem one of compromise, my spirit is not. Let the group or the individual bear our hospitals' responsibility as the evolution in any community or its hospital dictates. Show care in the selection of the individuals, however, that they be in intellectual sympathy and speak the common language of truth. Let responsibility be tangible—best, individual; but, if grouped, preserve personality. Finally, above all, remember: "These men are predestined: if a man love the labor of any trade apart from any question of success or fame, the gods have called him."

THE PURPOSE OF AN INTERNSHIP *

E. E. IRONS, M.D.
CHICAGO

Universities, medical schools and hospitals are interested jointly in the education of those who will care for the sick, and aid in the prevention and cure of disease. Of the students now in our medical schools, most will soon be engaged in some form of medical care of patients; some will enter administrative positions; others will devote their efforts to study and search for new facts in medicine perhaps entirely apart from patients; but no matter what their field of medical activity, all will be better men as well as physicians if they have the broadening experiences of a hospital internship.

The student entered his medical course after two to four years of study in college which included certain of the sciences, biology, chemistry, mathematics, physics and languages, and thereby presumably had some training in methods of study and thinking. The first two medical years, devoted mainly to the preclinical medical subjects, have given him a good training in the fundamentals of medicine. In his last two medical years he has been in contact with patients for more than half his time. The increased facilities of medical schools afforded by hospital clerkships and enlarged dispensary services, including obstetric services, have brought the student into close contact with patients during these two years, and he no longer receives his first introduction to actual patients on entering on his internship. He has studied to better advantage by reason of his clinical contacts, and is much better prepared up to this point for the practice of medicine than was the student of ten years ago. He is not a high school boy.

It is agreed that he now needs a hospital internship. What should this internship give him? First and foremost it should develop further his character, through close daily contact with attending men of high ideals. He should see by daily observation how honesty, sincerity, sympathy, are combined with knowledge and experience in dealing with the medical and surgical problems of each patient. Here in the hospital he sees more of the joy and of the tragedy of life than anywhere else in the world. He sees life at its best and at its worst, and while still in his formative years acquires that broad sympathy with humanity which physicians more than any others should and must have.

He learns how to get on with crabbed sick folk who might or might not be crabbed if they were well. He puts in practice what he has learned of the uses as well as the limitations of instruments of precision and of clinical and biologic tests, and gets a sense of relative values when he combines them with history and physical examination in the making of a diagnosis. He learns how to deal with difficult situations, involving diagnosis and treatment by meeting them himself under direction, and continually adds to his store of experience. It is obvious that in one or two short years he cannot see all the kinds of medical conditions which he will meet during his coming years of practice. He sees many examples, and above all he acquires methods of approach and observation. He learns to work in cooperation with others and to take his place in the team. He learns to use his hands and his senses. His education has just begun, to continue all through his years of professional life.

---

* Read before the Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 16, 1926.

Such an opportunity is essential to his further development, whether he is planning to devote himself to medical research or to some form of medical practice.

The hospital that best fulfils its functions of caring for the sick and of educating its staff, nurses and the public offers to the interne the best opportunity for carrying out the purpose of an internship. In some hospitals, the organization of the staff and the relations of the several departments to one another are best suited to a rotational type of intern service; in other hospitals the organization calls for single services or combinations of services. The individual needs of hospitals as well as of students vary.

The purpose of a hospital internship is not to supply deficiencies of the medical curriculum nor to complete a medical education. It sometimes happens that those charged with the administration of the medical school are willing to comfort uneasy consciences with the thought that evident defects or lapses in this or that department of medicine will be remedied in the student's internship. Weak or inadequate instruction in practical obstetrics, for example, should be frankly charged against the medical curriculum rather than covered up in the hope that the student will secure a month or so of obstetrics in a rotational internship.

Nor is the function of an internship to make specialists. The essential foundation for a specialist is a wide general medical experience on which he may build his superstructure of special knowledge. It has been felt by some that the single medical or surgical service tends to direct young men toward early specialization. No doubt, if the internship itself were the deciding factor determining specialization, this tendency would probably be more evident in single than in rotational internships. A recent inquiry by Dr. Gatewood among more than 150 physicians who served nonrotational internships indicates that their choice of a special service was usually prompted by a desire to be associated with some physician, and that the nonrotational service itself was not a determining factor leading to specialization.

If the chief of a single service has high ideals for his specialty, he will outline a further long program for the aspirant which will insure a wide clinical experience. The fear that a year of internship in internal medicine or surgery may contribute to premature specialization seems unwarranted by facts. A much greater danger to both interns and patients is met in certain rotational hospitals whose internships are much sought after, because of the loose organization which allows interns to perform operations without necessary supervision.

The purpose of an internship is not primarily to afford opportunity for the formal investigation of a problem. Now and then the exceptional intern, usually more mature than the average, continues some inquiry already begun, or makes a creditable study of some clinical topic in which he becomes interested; but the duties of an intern in the study and care of his patients should have first claim on his time, and any additional available hours are usually best spent in needed outdoor recreation or in reading. The essentials of research concern the attitude of mind of the student, rather than the subject of the inquiry, and habits of thoroughness, of scientific curiosity and of careful observation may be acquired in the ward as well as in the laboratory. The atmosphere of research and of desire for knowledge and truth in the hospital will influence him daily in making and recording his observations, and may happily lead him to undertake further independent study during his later residence.

The purpose of an internship is not to make possible the operation of the hospital nor to assist the hospital in meeting the technical requirements of some standardizing agency, although the maintenance of satisfactory intern service by the hospital does aid it materially in attaining both these ends. The days when hospitals exploited their interns by exacting services which should be performed by orderlies are largely past, but there still remain in many of our better hospitals certain uncorrected errors, such as the overloading of interns with an enormous mass of routine laboratory examinations demanded by some medical services, or the assignment of one intern to so many surgical attending men that, by reason of the multitude of operations, he has insufficient time to study and examine his patients, or the appointment of two or three interns to care for hundreds of patients, thereby inculcating habits of superficial examination which too often grow uncorrected in the young physician as the years go on.

The intern is an important part of the great cooperative enterprise of the modern hospital. He will work faithfully and grow in professional stature, if he is not overloaded, and if he is early led to enter into that spirit of friendly cooperation between attending staff, nurses, administration and patients which characterizes the well ordered progressive hospital, a spirit that may be described as a hospital consciousness.

A number of questions arise in the selection and organization of hospitals in which the student is to carry out the purpose of the internship, among which are methods of supervision of this internship and the kind of internship that is likely to be most satisfactory. Some medical schools have undertaken to supervise one year of the internship by requiring a fifth or hospital year as a prerequisite to the medical degree, and delegating the supervision of this year to a group of faculty members usually called the fifth year committee. This arrangement assures that all students will take internships in hospitals complying with certain minimum standards, and thus protects some of the less critical students from errors in selection of their hospitals. Fifth year committees have incidentally been of great assistance to hospitals, in pointing out, and in helping them to remedy, their defects. The administration of a fifth hospital year is, however, only one of the ways in which the student may be launched on his career on leaving the medical school, and there are those who prefer to have the supervision of the medical school cease at the end of the four years of study.

There has been much discussion as to whether a rotational internship should be insisted on for all students, and some states have gone so far as to prescribe the character of the internship and the time to be devoted to medicine, surgery and obstetrics. It will probably be admitted by all that the organization and administration of a majority of hospitals in this country are best adapted to a rotational service, and that even in hospitals offering single longer services a combination of two services is frequently desirable for the intern. But the needs of students are not all the same, and to insist that the education of every student shall conform in all its details with one rigid standard tends to reduce the ideals of professional education to the dead level idea of the trade union. Standardization has done much for medical education and for hospitals, and makes possible large results with minimum effort; but quantity production never produced a new model.

The suitability of a hospital for the purpose of an internship depends on the ideals and character of its staff, on the ability and desire of its administration to provide the best care possible for the sick, and on the presence of a spirit of inquiry and progress, and not primarily on whether it has a rotational or a nonrotational system.

IMMUNIZATION AGAINST DIPHTHERIA

WITH TOXIN DETOXIFIED WITH SODIUM RICINOLEATE

W. P. LARSON, M.D.
AND
HOWARD EDER, M.D.
MINNEAPOLIS

The present paper is the outgrowth of work begun by one of us[1] in 1919 on the effect of the surface tension of the culture medium on bacterial growth. In a series of papers published since then it has been shown that bacteria may be divided into two main groups with respect to their behavior toward surface tension depressants: one group, which is represented by the colon-typhoid organisms, grow well in mediums of low surface tension, while the other group, represented by pneumococci, streptococci and the tubercle bacilli, are extremely sensitive to slight lowering of the surface tension of the medium. In fact, members of the latter group are rendered nonpathogenic by exposure for short periods of time to proper surface tension depressants, such as sodium ricinoleate.

In attempting to find the most suitable surface tension depressant for biologic work, it was found that sodium ricinoleate served this purpose better than anything else tried, since it could readily be purified from castor oil, is very soluble in water, is active in reducing the surface tension in the p_H ranges of culture mediums, and gives solutions of low viscosity. Other soaps, especially of the unsaturated fatty acid series, may also be used, but none measure up to the salt of ricinoleic acid. We have therefore used sodium ricinoleate in most of our experimental work.

Having found that many pathogenic bacteria, such as pneumococci and streptococci, were rendered noninfective by treatment with sodium ricinoleate, Larson and Nelson[2] studied its effect on bacterial toxins. They found that tetanic toxin and diphtheritic toxin were instantly detoxified in a solution of purified castor oil soap when mixed in the proper ratios.

Although the toxins are instantly detoxified when appropriately mixed with sodium ricinoleate, their antigenic properties remain unimpaired. This observation suggested the possibility of using this method to modify bacterial toxins for immunizing purposes. All known bacterial toxins are too toxic to be used in public health work without first being modified so as to be rendered nontoxic. The sodium ricinoleate method proved to be valuable since it promptly detoxifies the toxin without altering its antigenic properties. In studying the immunizing properties of toxins modified in this way, Larson, Nelson and Evans[3] found that guinea-pigs and rabbits could readily be immunized against both tetanic and diphtheritic toxins with such material. It was found, however, on further investigation, that botulinic toxin formed the exception to the rule, since its toxicity was not perceptibly modified by sodium ricinoleate.

It has long been known that botulinic toxin differs in one respect from diphtheritic and tetanic toxins, in that it is not "destroyed" in the digestive tract as are the latter two. The observation that animals otherwise sensitive to diphtheritic and tetanic toxins cannot be intoxicated when these toxins are introduced into the digestive tract may possibly be explained by the action of the bile. The bile soaps undoubtedly detoxify these toxins, while botulinic toxin is not so changed. This is in full agreement with clinical observation. Indeed, the alimentary canal constitutes a thirty-foot culture tube teeming with unnumbered varieties of bacteria, some of which are undoubtedly producing toxins constantly. Had nature failed to provide an effective detoxifying mechanism, the host would probably not survive. Further investigation may reveal that this is one of nature's mechanisms for facilitating the development of a "natural" immunity to many of the bacteria to which man and beast are daily exposed. Some such mechanism must be of vital importance to the new-born.

The question as to the nature of the reaction between the toxin and soap is an interesting one, but one which cannot definitely be answered until we know something of the chemistry of the respective toxins. This question has been attacked by Larson, Halvorson, Evans and Green,[4] who conclude that the reaction is an adsorption phenomenon. It is, we realize, impossible at present to draw a sharp line between chemical reactions and some of those reactions which physical chemists consider to be of a purely physical nature. In fact, there are today many able chemists who deny the existence of adsorption phenomena in the sense of a purely physical combination. Whatever the nature of the reaction may be, it has been found that soaps—chiefly of the unsaturated fatty acids—and preferably sodium ricinoleate, detoxify bacterial toxins, with the exception of botulinic toxin, and that such soap-toxin mixtures are antigenic.

Having found that experimental animals, as rabbits and guinea-pigs, may be immunized with such detoxified toxins, it was then tried on human subjects. A group of laboratory workers and volunteer medical students were first injected subcutaneously with varying amounts of sodium ricinoleate solutions to determine whether the soap caused any reaction. It was found that solutions of highly purified sodium ricinoleate caused no reaction other than a slight burning sensation at the point of injection, which lasted only a few seconds. Diphtheria toxin-soap mixtures were then injected into a group of laboratory workers who had been found to be Schick positive, each subject receiving 0.125 L + toxin in a 1 per cent soap solution in a total volume of 1 cc. The injections were followed by a mild local reaction, which followed the course of an ordinary positive Schick test. A preliminary report of this work has been made by Larson, Eder and Hancock.[5] In our later work we have used 2 per cent soap solutions, and made the injection intramuscularly, and have, in this way, eliminated the reactions. If immunization against diphtheria is ever to become universal, it is imperative that a technic be developed which will eliminate local and general reactions, that the toxin be neutralized with substances which are nonantigenic, since the naked toxin cannot be used, and that the number of injections be reduced—preferably to a single treatment—and, further, the time required for immunity to develop should preferably be shortened to the point at which active immunization may be used to suppress an existing epidemic. The desirability of eliminating the antitoxin from the immunizing material is apparent to all because of the danger of sensitization to horse serum. The anaphylactic reaction which may result from the use of antitoxin in a case which has been treated recently with toxin-antitoxin is to be avoided in cases which are already toxic as a result of an infection. Stewart[6] has recently emphasized this point. There has been a tendency on the part of some authors to minimize the danger of sensitization. We admit that the small amount of serum that is given with toxin-antitoxin is not likely to produce a severe anaphylactic reaction. However, it is sufficient to sensitize against the respective serums. It is this sensitization which is undesirable should it be necessary to give serum from the same species of animal to an individual who is already toxic from some infection. Recognizing this objection to the original toxin-antitoxin, efforts have been made recently to substitute antitoxin prepared from goats, since goats are not generally used in the preparation of commercial antitoxins. This is without doubt a step forward, but it will not entirely eliminate the danger of anaphylaxis, since it is now known that serums of different animals may contain common proteins. Friedberger and his pupils have proved this beyond any doubt.

Immunization with Soap Toxins in Diphtheria

Number of Cases Treated	Number of Cases Re-tested	Time of Retest, Weeks	Dose, L +	Number of Treatments	Number Negative	Per Cent Negative	Per Cent Soap	Volume, Cc.
576	54	8	0.125	1	36	66.6	1	1
	4	6	0.25	1	4	100	2	1
	23	12	0.125	2 (7 day interval)	11	47.8	1	1
	70	5	0.18	1	27	38.5	2	1
Total...	151	12			76	52		

The use of sodium ricinoleate as the detoxifying agent eliminates the danger of sensitization to foreign substances, since it is not antigenic. In this age of serums and vaccines, the importance of this point cannot be overemphasized. Until the time arrives when antitoxins can be purified to the point at which their use will not sensitize the patient to animal serums, their use should be reserved for emergencies.

Whatever the technic of antidiphtheritic vaccination may be, it is imperative that the injections cause little or no reaction. The sodium ricinoleate method of modifying the toxin is equal to antitoxin in this respect. Another most desirable improvement in the technic would be reducing the number of injections, preferably to one treatment. Since antidiphtheritic immunization is so slow in getting under way, it may not be possible to meet this condition in all cases, although, as may be seen from the accompanying table, it appears not to be an impossibility.

After having satisfied ourselves that diphtheritic toxin-soap was fully equal to, and in many respects superior to, toxin-antitoxin as an immunizing agent, we felt that we should thoroughly investigate the possibility of immunizing with one treatment and, further, to determine the optimal interval between treatments for the best results, should repeated injections seem necessary. We have therefore given but one injection in the group of cases we are reporting, in order to study the maximum effect resulting from such a treatment. The subjects were institutional patients, largely of school and preschool ages. Unfortunately for this type of work, the patients do not remain in the institution for more than a few weeks at a time, which makes observation and retesting difficult. This circumstance accounts for the fact that only about 25 per cent of the subjects treated have been retested.

The accompanying table shows that immunity developed in 38.5 per cent of our cases within five weeks following one injection. In fact, we have seen a Schick test turn from positive to negative in ten days. In another group of 54 cases, 66.6 per cent became negative to the skin test in eight weeks. This was undoubtedly a particularly favorable group, and apparently a higher average than can be maintained using the present technic, since only 52 per cent of a larger group of 151 cases gave a negative test after twelve weeks. However, the fact that a 1 per cent soap solution was used instead of a 2 per cent may be a factor. This percentage of negatives will undoubtedly rise very considerably during the next three months.

Repeating the number of injections does not seem to increase the number of negative skin tests within the first twelve week period. Out of a group of twenty-three subjects given two injections at an interval of seven days, only 47.8 per cent gave negative tests twelve weeks from the time they received the first treatment. Retests which are now under way indicate that the percentages of negative skin tests will be very much higher at the end of the six month period.

There will undoubtedly be a considerable number of cases which will not immunize from a single treatment. We are then confronted with the problem as to the optimal interval between treatments for best results. We have, largely by force of habit, fallen into the routine of repeating vaccine treatments about a week apart. Since diphtheritic immunization is slow in getting under way, it would seem more logical to give the second treatment—when necessary—after a longer interval. We plan to make a more complete report on this point, as well as on other unsettled phases of the problem, in a future article. It is realized that the number of cases in our series is small. However, we feel we have shown that the sodium ricinoleate method is practicable and safe. The soap-toxin mixtures are, we believe, superior antigenically to toxin-antitoxin, and are free from the shortcomings of the latter. On the basis of the results reported in this paper, and elsewhere, we do not hesitate to recommend the sodium ricinoleate method as safe and effective in immunizing against diphtheria.

6. Stewart, C. A.: Anaphylactic Reactions Following Administration of Serums, J. A. M. A. **82**: 113 (Jan. 9) 1926.

Chickenpox First Described by Heberden in 1767.—In his essay on the death of Louis XV, published in 1774, he suggests that the king's first supposed attack of smallpox at the age of 14, thirty years before his death from this disease, was really "petite vérole volante, which is not smallpox properly so-called." It is noteworthy that varicella, which the term "petite vérole volante" signifies, was first clearly distinguished from smallpox in 1767 by Heberden in the medical transactions of the College of Physicians, which it is possible that Voltaire, owing to his interest in medical literature, may have read. Elsewhere (Précis du Siècle de Louis XV, Chap. XII) he says that the king's attack was of the putrid or malignant type, and that several of his officers contracted the disease from him and died.—Rolleston, J. D. *Proc. Roy. Soc. M.* **19**:84 (Feb.) 1926.

IMMUNIZATION AGAINST SCARLET FEVER

WITH TOXIN DETOXIFIED WITH SODIUM RICINOLEATE

W. P. LARSON, M.D.
E. J. HUENEKENS, M.D.
MINNEAPOLIS
AND
WOODARD COLBY, M.D.
ST. PAUL

In the paper on immunization against diphtheria with toxin that has been detoxified with sodium ricinoleate,[1] a brief discussion of the action of soaps on bacterial toxins was given and references to previous publications were cited. We have therefore not deemed it necessary to repeat the discussion here.

In immunizing members of the human family against any bacterial toxin, it is necessary to have the immunizing material in a form that will give little or no reaction, as any immunizing method that is followed by a moderately severe reaction, either general or local, will not find favor with either the physician or the general public. In fact, when animal immunization against bacterial toxins was first begun, following the discovery of diphtheritic and tetanic toxins, it was found that the naked toxins were too toxic to be used in the preliminary injections. Efforts were therefore made to find some neutralizing agent that would lessen their toxicity without altogether destroying their antigenic properties. Roux and Yersin found iodine trichloride of value for this purpose. Later, antitoxin replaced the iodine salt.

In immunizing horses against bacterial toxins, in the preparation of antitoxin, it is customary to begin treatment either with a toxin-antitoxin mixture or by giving the animals an injection of antitoxin preparatory to injecting the toxin. This procedure is followed until the animals have acquired a "ground" immunity, after which they may be hyperimmunized by injecting the unmodified toxin.

Since it has not been found practical to begin animal immunization with the unmodified toxin, it would seem the more unpractical to attempt to immunize members of the human family with toxins that had not been modified so as to render them less toxic. We believe that the experiences of those who have used the naked scarlet fever toxin in graduated doses in attempts to immunize against scarlet fever support this view. General immunization against scarlet fever will probably never receive the enthusiastic support of either the physician or the general public until a method is found of modifying the toxin, so that little or no reaction will follow the treatment.

As was pointed out in the preceding paper, certain fundamental conditions must be met before any prophylactic treatment will come into general use. A method that requires numerous injections is too cumbersome to be practicable. The treatments must be brought down to a minimum, preferably one treatment; they should be followed by little or no reaction, and, to be ideal, the immunization period should be shortened to come within the incubation time of the infection, as in the case of rabies.

The ideal procedure should further enable us to suppress an existing epidemic. From the public health standpoint it is more important, in our opinion, to be able to suppress an epidemic than to give a permanent immunity, although the latter is most highly desirable.

In the work reported in this paper, we feel that we have met many of the conditions for an ideal method of immunization. By using toxin that has been detoxified with sodium ricinoleate, we have modified the toxin without altering its antigenic properties, so that a large dose of the toxin may be given without producing toxic effects. The detoxifying agent is not antigenic, and hence there is no danger of sensitizing the patient to foreign serums. By using a nonantigenic detoxifying agent, we are independent of time intervals, as well as the previous history of the patient, should reinjections seem desirable.

The so-called scarlet fever antitoxin will not serve as a detoxifying agent for purposes of immunization since the "neutral" mixture is not always stable. The "neutral" soap toxin mixtures, on the other hand, are stable, and, so far as can be determined, remain so indefinitely if properly prepared and stored.

Immunization with Soap Toxins in Scarlet Fever

Number of Cases Tested	Number of Cases Positive	Dose	Time of Retest, Days	Per Cent Negative	Time of Retest, Days	Per Cent Negative
1,542	536	.....	..	....	...	..
	18	1,000	5	48	180	70
	39	1,500	7	64.5		
	44	2,000	8	68.5		
	318	3,000	8	77.3		
	68		21	97		
	191		60	80.6		
	21	4 000	8	90		
	5	4,500	8	100		
	2	5,000	..	....		
	2	10,000	..	....		

The importance of using a detoxifying agent such as sodium ricinoleate, which reacts with all toxins, is apparent in view of the recent work of Park and Spiegel,[2] who have shown that scarlet fever toxin is not a distinct entity, as are diphtheritic and tetanic toxins, but that a given strain of the scarlet fever streptococcus may secrete four or more toxins which are unrelated antigenically. The sodium ricinoleate method enables us to detoxify all streptococcic toxins, irrespective of groups, to the point at which large immunizing doses may be given without causing objectionable local or general reactions.

Intramuscular injections of from 3,000 to 5,000 skin test doses are followed by little or no reaction. Children over 12 years of age and adults seem to be slightly more sensitive to the toxin than younger persons.

In our work we have prepared the toxin-soap so that the desired amount of toxin was contained in a volume of 1 cc.

The importance of mixing the toxin and the soap in proper ratios has been emphasized by Larson, Halvorson, Evans and Green.[3]

In the work here reported only Dick-positive cases have been treated. We have used 3,000 skin doses in most of our work, since this amount of toxin was found to give a high percentage of immunity, as determined by the skin test, in a relatively short period of time.

The accompanying table indicates that the acquisition of an immunity varies, within certain limits, directly with the size of the dose of toxin, although not all age groups respond to the toxin in the same degree.

---

[2] Park and Spiegel: J. Immunol. **10**: 829-833, 1925.

[3] Larson, Halvorson, Evans and Green: Colloidal Symposium Monograph, Chemical Catalog Company, 1925.

The larger amounts of toxin—from 3,000 to 4,000 skin test doses—give an apparent immunity in from 77.3 to 90 per cent of the cases within eight days following the treatment.

This suggests the possibility of using active immunization in fighting a threatening epidemic. In fact, we have successfully used this method to suppress several outbreaks of scarlet fever in institutions. A detailed report of this work will be published soon.

As regards the duration of the immunity, we have found that 70 per cent of those who gave a negative skin test within eight days following the small dosages were still negative at the end of six months. It is not improbable that repeated injections of increasing doses may be necessary for the establishment of a permanent immunity. It is not possible, however, to draw conclusions on this phase of the problem at the present time.

Our table shows that only 80.6 per cent of a group of 191 were negative sixty days after the treatment. The average age of this group was nearly 20 years. This probably accounts for the lower percentage of negative Dick tests.

The work of Park and Spiegel shows clearly that a person may be immune to a given toxin and still not immune to all scarlet fever toxins. Their observations emphasize the necessity of using a polyvalent antigen in the immunizing material in order to protect the patient against the widest possible variety of toxins.

On the basis of some work we have already done, we have come to the conclusion that the antigen should contain not only the scarlet fever toxin, but the streptococci as well, in order to develop an antibacterial as well as an antitoxic immunity. Such an immunity should provide a double security against scarlet fever. It is without doubt an antibacterial immunity that follows antityphoid vaccination.

SUMMARY

Sodium ricinoleate is an effective agent in detoxifying scarlet fever streptococcic toxins, and such soap toxin mixtures give a rapid immunity without causing objectionable reactions. The sodium ricinoleate method of detoxication makes it possible to give sufficient toxin in a single injection to cause positive skin tests to become negative within a few days. It opens the possibility of suppressing an epidemic of scarlet fever by active immunization, since 77.3 per cent of positive skin tests become negative in eight days, and 97 per cent become negative in three weeks.

Chinese Medical Sayings and Proverbs.—1. Do not take medicine compounded by a doctor who is not backed by the experience of three generations. 2. To become a good doctor requires breaking the arm three times. 3. However well up one is in Wang Su-ho, it is not so good as more clinical practice. (Practice makes perfect.) 4. To be a caligraphist, requires the wasting of paper; to be a doctor, requires the sacrificing of lives. 5. Wide reading increases knowledge of diseases; more clinics give experience in diagnosis; repeated tests make properties of drugs better known. 6. The skilful doctor knows what is wrong by listening alone, the middling doctor by observation, and the inferior doctor by feeling the pulse. 7. Curved wood is found in abundance at the skilful carpenter's shop; crowds of patients are seen at a good doctor's office. 8. Doctors cannot cure their own complaints.—*China M. J.* 39:1100 (Dec.) 1925.

A BENIGN AND CURABLE FORM OF HEMORRHAGIC NEPHRITIS *

GEORGE BAEHR, M.D.
NEW YORK

Acute hemorrhagic nephritis, which commonly follows scarlet fever and other forms of acute streptococcus angina, is a disease of serious prognosis, for it not infrequently leaves behind it a more or less severely damaged kidney in which all the glomeruli present evidences of a diffuse injury. As a result, the acute nephritis may gradually progress to a chronic diffuse nephritis involving the glomeruli, the tubules and interstitial tissue.

In contradistinction to this well known type of acute hemorrhagic nephritis there occurs a benign form with which most clinicians are as yet unacquainted. Attention was first seriously called to its existence by the German clinicians Scheidemandel[1] and Volhard,[2] but in the English and American literature nothing more than extremely casual references have come to my notice.

I have had the fortunate opportunity of studying fourteen cases of this benign type during the last five years. Briefly summarized, the disease occurs most commonly in young adults and is characterized by a hematuria, usually macroscopic, which may be painless. Unlike the common form of the acute diffuse disease, there are usually no constitutional symptoms. Neither edema nor hypertension develops at any time during the course. The hematuria may be persistent or recurrent in the form of brief attacks. In most instances a definite focus of chronic infection can be discovered, usually in the tonsil. The elimination of such a focus, for example by tonsillectomy, frequently results in a temporary but pronounced increase in the hematuria, followed by gradual but complete disappearance of red blood cells from the urine.

Many of the cases are at first considered examples of hematuria due to surgical conditions in the genito-urinary tract. Some have undoubtedly masqueraded in the past under the general term "essential hematuria."

INCIDENCE

The youngest patient in my series was 15 years of age; the oldest, 42. Eight of the fourteen patients were young adults in the third decade of life. In fact, in my experience the disease was rather strikingly limited to young adults. There seems to be no predilection for either sex. Some of the cases were encountered in private practice, although the major experience has been obtained in the wards of the hospital.

COURSE OF THE DISEASE

There are two types of the disease which differ from each other both in their mode of onset and in their course.

Recurrent Type.—The hematuria in this type usually lasts only a few days. The intervals between attacks are variable, being weeks, months or years, and during this period the urine may be entirely normal or may at times show some red blood cells on microscopic examination. The acute angina which usually precedes the attack consists generally of a diffuse redness of the pharynx, the pillars of the fauces and perhaps the tonsils, although in some instances a true follicular tonsillitis has been observed. The discomfort caused by the sore throat is usually not very great. The hematuria follows the angina at a variable period of time, from one to eight days after its onset, most commonly, however, within one or two days after the appearance of the sore throat.

---

* From the Department of Medicine, Mount Sinai Hospital

1. Scheidemandel: München. med. Wchnschr. 60: 1778, 1913.

Persistent Type.—This type of the disease is more insidious in onset, and often the hematuria is accidentally discovered by the patient who is otherwise entirely well. The macroscopic hematuria may vary in intensity from a slight reddish turbidity of the urine to a deep smoky appearance. In the more chronic cases it may persist for many months or until surgical intervention. The most striking characteristic is the complete absence of subjective symptoms in spite of the pronounced hematuria.

In this persistent type of the disease, the patients are seldom conscious of sore throat. The past history may reveal frequent attacks of pharyngitis or tonsillitis, but during the actual course of the hematuria most patients do not experience any throat discomfort. A few admit, on questioning, that they feel a slight throat irritation.

URINARY FINDINGS

Aside from the macroscopic hematuria, the urine otherwise presents few changes. The specific gravity is normal and the kidneys still possess a normal capacity to concentrate the urine during the night. Albumin is always present in variable amounts, from a faint trace to a cloud. The most conspicuous microscopic finding is the presence of innumerable red blood cells, but all kinds of casts may be found, both red cell casts and hyaline and granular casts. The casts are more or less obscured, however, by the presence of the enormous numbers of red blood cells. The total volume of urinary excretion remains unchanged.

PAIN AND OTHER SYMPTOMS

Although half the patients have had no pain or symptoms of vesical irritation, a few have occasionally complained of slightly increased frequency of urination. With the onset of the hematuria and at times during the course of the disease, the patients may experience a dull pain in one or both lumbar regions, which occasionally may radiate around the front of the abdomen and into the groin. This lumbar pain is seldom conspicuous and is usually brought to light only on questioning the patient.

Besides the hematuria and in some patients the slight lumbar pain, there are few conspicuous symptoms. As has been said, sore throat usually precedes the onset of the hematuria in the recurrent type of the disease, whereas in the more chronic persistent cases there may be little or no discomfort. Examination of the throat reveals in most instances chronically diseased tonsils, which may or may not be hypertrophied. On pressure, purulent material can usually be expressed from one or both tonsils. Occasionally the pus is thin and brownish, while at other times it is thick and creamy. In the present series a thin, brownish pus was more common.

The blood pressure always remains normal. Edema has never occurred in any of the patients. Chemical examination of the blood has regularly revealed only normal findings. Not even the slightest increase in the nitrogen constituents of the blood has ever been detected. None of the patients have shown an appreciable anemia. The phenolsulphonphthalein, the indigocarmine, the Mosenthal and other renal function tests have all been normal. In fact, except for the hematuria and albuminuria, a study of the renal function has never shown any deviation from the normal, even in the cases in which macroscopic hematuria persisted for many months.

ETIOLOGY

In the acute recurrent cases which have been preceded by a diffuse redness of pharnyx and tonsils, streptococci may regularly be found in smears and cultures from the throat, but no work has yet been done to ascertain definitely whether they have any causative relation to the condition. Nor have the organisms been studied serologically in order to ascertain whether they fall into a common group. It is therefore impossible as yet to say that they do not merely belong to the common flora of the mouth. In the persistent types of the disease, smears and cultures from the purulent material expressed from the tonsils either before or after tonsillectomy usually show the presence of an anhemolytic streptococcus.

In one of my patients the focus of infection was apparently in the antrum of Highmore. Evacuation of the pus which contained streptococci, and frequent washings until the infection had completely subsided, were followed by disappearance of the hematuria.

In one patient in whom no focus of infection was discoverable either in the tonsils or in the sinuses, a chronic pulmonary tuberculosis was present with cavitation in the right upper lobe. It is quite possible that in this instance a secondary infection of the tuberculous cavity was the source of the trouble. Volhard observed a similar case.

PATHOLOGY

In view of the fact that the disease is always benign, I have had no opportunity of studying the kidneys histologically. Volhard believes that the pathologic lesion is probably a focal disease of the kidneys. As he pictures it, occasional glomeruli are constantly being damaged either in whole or in part. Unlike the ordinary diffuse glomerulonephritis, the vast majority of glomeruli are still intact.

The lesion is probably not unlike the embolic glomerular lesions which were first described by Loehlein,[3] and which I studied rather extensively some years ago.[4] These embolic glomerular lesions are almost constantly to be found in the kidneys of patients dying of subacute bacterial endocarditis due to the anhemolytic streptococcus. I was able to show by bacterial stains that the damaged loops of the affected glomeruli often contain bacterial emboli.

However, the focal glomerular lesions of this benign hemorrhagic nephritis need not necessarily be the result of an embolic process. Some experimental studies on glomerulonephritis would seem to indicate that identical focal lesions affecting only parts of occasional glomeruli may also be produced by a purely toxic process.[5] I have also twice observed such focal glomerular lesions in the kidneys of patients in whom no endocarditis existed. Neither patient had been seen during life, so that it is impossible to state whether at any time they had presented the clinical picture of benign hemorrhagic nephritis.

DIFFERENTIAL DIAGNOSIS

Embolic Glomerular Lesions of Subacute Bacterial Endocarditis.—The focal embolic glomerular lesions of subacute bacterial endocarditis are accompanied by no clinical evidences of renal disturbance beyond hematuria and perhaps slight albuminuria. The hematuria is usually discovered only on microscopic examination. Macroscopic hematuria is rarely seen and is then more commonly the result of gross infarctions of kidney parenchyma by larger emboli thrown off from the vegetations. On the other hand, patients with a benign hemorrhagic nephritis generally present a gross macroscopic hematuria. They are otherwise well, presenting no evidences of cardiac disease.

Acute and Subacute Diffuse Glomerulonephritis.—The acute diffuse glomerulonephritis which follows scarlet fever and streptococcus angina (and which may also occur as a complication of subacute bacterial endocarditis due to the anhemolytic streptococcus [6]) presents a much more important problem in differential diagnosis.

The patient should be observed daily for puffiness of the eyelids, as the edema may be transient, occurring only for a few days. Similarly, the blood pressure should be taken every day, for in mild cases of acute diffuse glomerulonephritis an elevation in blood pressure may occur only on one or two days during the first week of the disease and may be entirely overlooked. Later, of course, if renal injury should lead to a chronic diffuse nephritis, hypertension will again be observed, but this may be months or years later. A chemical examination of the blood should be made when the patient is first seen. The fluid intake should be measured and compared with the total volume of the twenty-four hour urinary excretion. If a patient develops hematuria and also presents any evidences of edema, arterial hypertension, disturbances in renal function, or an increase in the nitrogenous constituents of the blood, the possibility of a benign focal hemorrhagic nephritis may be eliminated immediately from consideration. The patient is suffering from a diffuse vascular injury.

Scheidemandel[1] has also observed that the increase in hematuria which follows within twenty-four hours after tonsillectomy in so many of the cases of benign hemorrhagic nephritis constitutes a striking therapeutic criterion of differential diagnostic value. Curiously enough, such a phenomenon is rarely observed after tonsillectomy on patients suffering from diffuse glomerulonephritis.

Surgical Conditions.—The most important surgical conditions that may be associated with hematuria are renal or ureteral calculi, neoplasms of the kidney, papillomas of the kidney pelvis, ureter and bladder, and tuberculosis of the genito-urinary tract. Cases of benign hemorrhagic nephritis, in which the patient experiences some discomfort in the lumbar region, will always give rise to the suspicion that we are possibly dealing with a renal or ureteral calculus or some neoplastic disease of the kidney or ureter. In such instances, roentgen-ray examinations and cystoscopic studies made by a competent genito-urinary surgeon are needed before one can arrive at a differential diagnosis.

Eight of my cases have been studied by ureteral catheterization and renal function tests. The hematuria was found in all instances to be bilateral. In view of the focal character of the disease, with only occasional glomeruli involved, it is quite conceivable that the disease may at times be unilateral or that the hematuria and albuminuria may be more marked on one side than the other. Examples of unilateral nephritis have been described in medical literature, and they may possibly be examples of this disease, i. e., benign hemorrhagic nephritis, rather than the more common acute diffuse glomerulonephritis.

PROGNOSIS

The prognosis is excellent. Even patients in whom the hematuria has lasted continuously for many months have not shown the slightest evidences of a disturbance in renal function. Volhard is of the opinion that the condition, if unrecognized or allowed to continue indefinitely, may eventually lead to such extensive glomerular damage that disturbances of renal function will occur and the clinical picture of a chronic diffuse nephritis develop. I have as yet had no such experiences and cannot, therefore, confirm this important statement. It is quite likely that the patients who eventually develop evidences of renal insufficiency have primarily mild cases of the ordinary acute diffuse form of glomerulonephritis.

The following case history will exemplify this point and will also illustrate the characteristic course of the disease:

REPORT OF CASE

A woman, aged 22, who had always been in perfect health except for occasional attacks of tonsillitis in past years, discovered accidentally that the urine was bloody. On rare occasions there was a dull ache in one or both lumbar regions, but this was not very conspicuous. The hematuria persisted, and she consulted her physician, who came to the conclusion that she had a ureteral calculus. Blood pressure was normal, and there were no constitutional disturbances. Urinary frequency both day and night was not increased, and the volume of urine excreted did not differ from the normal. She then consulted a genito-urinary surgeon, who on several occasions performed a cystoscopy and catheterized the ureters. Even on cystoscopy and before the introduction of the ureteral catheters, it could be observed that a hemorrhagic urine was entering the bladder from both ureteral orifices. Catheterization of the ureters, a study of the urinary excretion from both kidneys, functional tests of the kidneys, roentgen-ray examinations and pyelograms failed to reveal a calculus or other surgical condition. The urine continued to contain macroscopic blood, a cloud of albumin and a few hyaline and granular casts, so that the physicians were forced to the conclusion that the patient was suffering from a hemorrhagic nephritis.

At this time she came under my observation, and all the studies previously made to exclude surgical disease of the kidneys and ureters were again made, with negative results. Frequent blood pressure observations over several months revealed only normal findings, the blood pressure never rising above 120 mm. of mercury. The patient was put to bed for a three week period, but without any material change in the intensity of the hematuria. There was often some slight daily variation, but macroscopic blood was constantly present in the urine.

Both tonsils were hypertrophied and conspicuously diseased. On pressure, considerable thin brownish pus could be expressed. After six months of dietetic and other therapy, the patient consented to the removal of her tonsils under local anesthesia. The tonsils were studied bacteriologically and pathologically. Cultures of an anhemolytic streptococcus were obtained. Microscopic sections revealed purulent accumula-

---

tions within and about the crypts. Within thirty-six hours after the removal of the tonsils under local anesthesia, a very pronounced increase in the hematuria took place, the urine presenting a dark smoky appearance. This persisted for another twenty-four to thirty-six hours and then gradually subsided. Two and a half weeks after operation, macroscopic blood had disappeared from the urine, and three and a half weeks after the operation no more red blood cells could be found even on microscopic examination. A faint trace of albumin could occasionally be found in some examinations.

After the tonsillectomy, the patient asked advice concerning the advisability of marriage. On the basis of previous experience concerning the essential benignity of the pathologic process, it was thought safe to advise her that she was probably cured. Two years later she reported that she had become pregnant and asked advice as to the desirability of terminating the pregnancy. No red blood cells had reappeared in the urine in the interim, although at times a faint trace of albumin could be found. Phenolsulphonphthalein and other tests for urinary function again revealed that the kidneys were entirely normal. She was advised, therefore, to continue the pregnancy and she passed through the entire nine months without showing the slightest evidences of any renal disturbance.

COMMENT

In other words, the kidneys of this patient, in whom the disease had lasted continuously for six months, were put to a most severe functional test two years later and proved to be normal. It is evidently important to be able to differentiate this group of benign focal hemorrhagic nephritis from the larger and more malignant group of acute diffuse glomerular disease.

Clinical Notes, Suggestions, and New Instruments

SPORADIC TRICHINOSIS WITH EXTREME HYPOTENSION *

Garnett Cheney, M.D., San Francisco

Sixty-six years ago, Zenker was the first to correlate certain symptoms in man with *Trichina spiralis* infection, and since then many cases have been completely reported both in this country and in Europe. The case here described presents an interesting problem in diagnosis and certain features little recognized as yet in America.

Report of Case

A Filipino cook, aged 25, unmarried, was brought to the hospital complaining of general weakness. He had lived in San Francisco for the past five years and had been well except for influenza seven years previously. Six months before, he was in a hospital following an injury to his head, but he had made a good recovery. Two weeks before entry, he began to feel weak and his legs seemed heavy. His only other complaints were a sharp subxiphoid pain, and a diarrhea the day before admission. He was unable to associate any dietary indiscretions with his present illness.

He appeared poorly nourished, apathetic and ill. The eyes, ears, nose and throat were not unusual; the anterior cervical glands were palpable; there was stiffness of the neck with pain on flexion. The lungs and heart showed no abnormalities; the blood pressure was 82 systolic and 46 diastolic. The abdomen was held rigid and was generally tender to palpation. The muscles of the arms and legs were tender to pressure; extension of the right forearm was limited and painful. The knee jerks were absent, and a bilateral Kernig sign was present.

The temperature at entrance was 38 C. (100.4 F.), the pulse 100 and the respirations 28. The blood at entrance and the day following showed a hemoglobin of 72 per cent; 10,000 and 14,500 white blood corpuscles, with a slight increase of polymorphonuclear cells in the differential count, but no eosinophils. Urine, feces and sputum were not abnormal. The Widal test and the blood culture were negative; the spinal fluid taken on the second day was normal; its examination as described by Meyer[1] revealed no larvae of trichina. Repeated careful examinations of the blood also showed no larvae, but a piece of the left pectoral muscle removed on the third day was invaded by trichinae, none being encysted.

The temperature varied between 37 and 39 C. (98.6 to 104 F.), gradually falling to normal at the end of the second week; the pulse ranged around 100, and the respirations between 20 and 30. On the second day, the blood pressure fell to 44 systolic and 18 diastolic, checked by three observers with different sphygmomanometers. One cc. of epinephrine was given subcutaneously, and the blood pressure rose to 110 systolic and 48 diastolic, gradually falling to a constant level of 70 systolic and 42 diastolic after six hours. It gradually rose during the remainder of the four weeks stay in the hospital, reaching 102 systolic and 64 diastolic at discharge. The patient lay in bed with the legs drawn up and increasing flexion of the right arm at the elbow, until it could not be extended more than to a right angle. Similar flexion of the left arm developed, and both biceps muscles became tender, hard and lumpy. On the third day, there was a leukocyte count of 23,500 cells with a differential count of polymorphonuclears, 46 per cent; lymphocytes, 12 per cent; eosinophils, 41 per cent, and transitionals, 1 per cent. As no eosinophils had been present on the previous day with a total white blood corpuscle count of 14,500, these characteristic cells had appeared as a sudden shower. The white count fell to 7,900 before discharge with only 1 per cent of eosinophils; the hemoglobin was only 42 per cent. At the end of the first week, the patient looked bad and complained of generalized muscular pains; at this time, the electrocardiogram showed occasional extrasystoles. From then on, he improved except for a tender enlargement of the cervical, axillary, epitrochlear and inguinal glands noted at the end of the second week; the spleen was not felt. These glands were barely palpable at discharge. The bowels were regular and the urine output good throughout the illness. After the diagnosis had been established, the patient recalled having eaten some partially cooked pork one week before he was taken sick. Two friends said to have eaten of the same pork had had no symptoms and had normal blood counts.

At entrance, the commonly mistaken diagnosis of typhoid fever was made, and epidemic encephalitis was considered. The absence of eosinophils in the blood during the first two days was considered strong evidence against trichinae but has been noted before in severe infections.[2] The myositis was undoubtedly responsible for the stiff neck, the absent knee jerks,[3] and the positive Kernig sign, and caused the striking, characteristic stereotyped contractions of the arm muscles. The hypotension has recently been described by Gruber[4] and other German writers, but not generally noted in this country. The rise in blood pressure following the injection of epinephrine is a distinct contradiction to the reports of Maase and Zondek,[5] who found that it produced no rise in their cases. It is remarkable that the day the blood pressure was 44 systolic and 18 diastolic there were no other signs of circulatory failure and that the urine output was normal. The adenopathy is an unusual occurrence. No specific treatment was given, as the literature revealed none of proved value in the later stages.

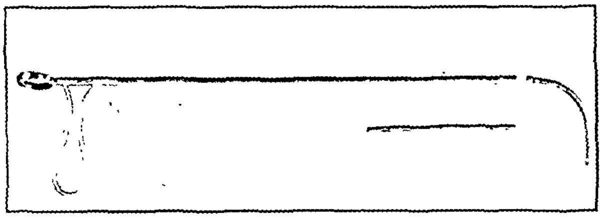
A NEW UTERINE SCREEN AND INTRODUCER FOR INSERTING RADON TUBES INTO THE UTERUS

FRANK EDWARD SIMPSON, M.D., AND ROY EMMERT FLESHER, M.D.,
CHICAGO

The screen consists of a hollow cylindric lead tube, which has a lumen just large enough to contain our radon (radium emanation) tubes. It can easily be bent to conform to the curve of the uterine canal, its flexibility being one of the important features. Screens may be made in various lengths and may contain from two to four or more radon tubes placed end to end. The screen containing two radon tubes is 5 cm. long, and each additional tube adds 1.75 cm. to its length. The wall thickness is 0.75 mm., the diameter of the lumen being 2.5 mm., and the outside diameter 4 mm. Each end of the screen is fitted with a nickel plated brass screw cap, which is provided with an eyelet through which a strong silk thread may be passed.



Screen and introducer.

The introducer is 30 cm. long and contains an obturator. One end of the obturator is divided into two jaws for the reception of the screen, the other end being provided with a ring. The screen may thus be clamped in the distal end of the introducer or released from it, by pulling or pushing on the proximal end of the obturator. The principle is the same as that used in the construction of the screen holders described by Simpson.[1]

ADVANTAGES

1. The screen can be bent to the required curve and introduced into the uterus, usually without bringing the cervix down.

2. The screen forms a radioactive rod of the desired length, so that the whole uterine canal may be effectively irradiated. From 500 to 1,000 or more millicuries may be used, the time of exposure being, approximately, from one to three hours, depending on the quantity of emanation.

3. In making intracervical applications in cancer of the cervix, dilation is seldom necessary. Trauma is thus minimized, and the danger of causing metastasis is probably greatly lessened. The same type of screen and introducer may be used in applying radium salts, but the increased bulk of a screen containing large quantities of radium salts would be a serious disadvantage. The lead screen, on account of its flexibility, has been found useful in treating other cavities. The screen can be straightened by being rolled between two smooth wooden blocks. After it has been bent and straightened a few times, it is liable to be inadvertently broken, but this danger may be obviated by frequently using a new screen.

Periarticular Fibrositis.—This is a special variety of a generalized fibrositis affecting the fibrous capsule of the joints. The characteristic lesion of fibrositis is the replacement of inflamed fibrous tissue by scar tissue, which is liable to contract. This contracture leads to thickenings which, if still the seat of inflammation, are tender and form nodules, and to shortening of the ligaments, which, if allowed to persist, pull on the ends of the opposing bones, resulting in deformities. In periarticular fibrositis there is no definite swelling of the joint, and the wasting of the surrounding muscles is that of disuse rather than of trophic disturbances. —Gordon, R. G.: *Brit. M. J.*, Jan. 9, 1926.

Special Articles

DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1925

The first annual summary of diphtheria mortality in the cities of the United States with a population of more than 100,000 appeared in THE JOURNAL in 1924.[1] The third summary, for 1925, is presented here. Population estimates are the same as those in the article on typhoid.[2] The number of deaths from diphtheria used in calculating death rates has been sent us in each instance by the local health authorities, and we are under obligations for the generally prompt response to our request. The geographic divisions of the U. S. Census Bureau are used as in previous years.

As in former summaries, we have not attempted to adjust diphtheria rates on the basis of age, sex or racial distribution of the population, although these factors are well known to have great influence on the crude rate. Our reasons for this are given in the second summary.[3]

The New England cities (table 1) for the most part had very low diphtheria death rates in 1925 as compared with the 1920-1924 average. New Haven, for the second successive year, reports the remarkably low rate of 1.7 and again stands among the best on the Honor Roll. Lowell also shows marked improvement. Worcester, which seems to have had something of a diphtheria epidemic in 1924, again brings up at the foot of the New England cities, although with a materially lowered rate (14.6: 23.0). Boston starts the new quinquennium with the lowest diphtheria rate in its history (12.7), a substantial reduction from its five-year average (20.2). Hartford, which for 1890-1894 lost annually 121 lives per hundred thousand from diphtheria, in 1925 did not lose four.

TABLE 1.—*Death Rates of Cities in New England States from Diphtheria (Including Croup) per Hundred Thousand of Population*

	1925	1920-1924	1915-1919	1910-1914	1905-1909	1900-1904	1895-1899	1890-1894

* Rate calculated on figures for population in 1922.

The cities in the Middle Atlantic states (table 2) likewise make an admirable showing, all but two having a diphtheria rate in 1925 below the 1920-1924 average. New York again reaches a low mark, a splendid tribute to the indefatigable efforts of the health department of that city. It is a piece of good luck for Camden, which brings up the tail of the column in typhoid this year, that it should be saved from the same ignominy in diphtheria by the maiden effort of Utica. In three other Middle Atlantic cities—Syracuse, Paterson and Buffalo—the 1925 rate shows a truly amazing decrease in comparison with the 1920-1924 average.

# The rate for Richmond was erroneously given as 2.2 in the diphtheria survey for 1924; the correct figure of 12.0 is used here.

The South Atlantic cities (table 3) had a somewhat checkered year, Richmond and Washington apparently suffering in 1925 from diphtheria more seriously than for some years, while the other four cities show a notable reduction.

† Data for 1891-1894

# Rate calculated on figures for population in 1924.

In the East North Central states (table 4) only two cities have rates greater than 10, and only one (Milwaukee) shows an increase—and that very slight—over the preceding five-year average. Several cities which, like Toledo and Detroit, have maintained relatively high diphtheria rates for two decades, achieved very low rates in 1925. Chicago had a rate of only 8.0, the lowest reported for any city with more than 1,000,000 population.

Table 5.—*Death Rates of Cities in East South Central States from Diphtheria (Including Croup) per Hundred Thousand of Population*

	1925	1920-1924	1915-1919	1910-1914	1905-1909	1900-1904	1895-1899	1890-1894

Omaha	11.8	22.9	35.8	15.8	24.5	20.5	28.2	82.9
St Paul	13.4	17.5	20.7	31.4	31.1	27.9	43.3	75.4
Minneapolis	25.0	13.4	19.9	28.3	24.4	44.6	34.0	55.0

* Data for 1912-1914

† Rate calculated on figures for population in 1924, with same annual increment added as in 1922-1923, 1923-1924.

The West North Central cities (table 6) with one exception showed material reduction in diphtheria mortality in 1925. Minneapolis evidently experienced a rather sharp epidemic which not only gave it the highest rate of any city for 1925 but the highest reported for the two years 1924-1925. The adjoining city of St. Paul had a 1925 rate only about half as great. Duluth, reporting for the first time, is apparently the first city of this size to pass a twelve-month period without a single diphtheria death.

Table 7.—*Death Rates of Cities in West South Central States from Diphtheria (Including Croup) per Hundred Thousand of Population*

	1925	1920-1924	1915-1919	1910-1914	1905-1909	1900-1904	1895-1899	1890-1894
Dallas	3.6	8.3	7.4	6.9	8.1	16.9	16.0	21.8
San Antonio	4.5	7.7	8.7	6.7	7.6	17.1	20.6	4.4
Fort Worth	5.8	1.8	....	....	....	....	....	....
New Orleans	6.8	6.5	11.6	19.6	10.2	11.5	17.1	51.3
El Paso	8.6	20.0	17.6	29.2	....	....	....	....
Houston	10.4	6.4	6.1	7.8	10.5	....	....	....
Tulsa	17.7	....	....	....	....	....	....	....

The cities in the West South Central states (table 7), where diphtheria mortality has apparently never been so severe as farther north, continue for the most part to have low rates. The newcomer in this group, Tulsa, however, qualifies among the ten worst in the country. Dallas, San Antonio and El Paso record much lower rates in 1925 than in 1920-1924, but Fort Worth, New Orleans and Houston show an increase.

The cities in the Mountain and Pacific states (table 8) show much greater divergence than last year: Portland, Salt Lake City, Spokane and Tacoma have higher rates, but Seattle, Oakland, San Francisco and Los Angeles have much lower. The fluctuations in this group of cities illustrate the need of caution in drawing comparisons for a limited period. All but one of the cities in this group had considerably higher diphtheria mortality in 1920-1924 than in 1915-1919, and all but two higher than in 1910-1914.

Cincinnati
Hartford
Jersey City
Newark
New York
Philadelphia

TABLE 12.—*Number of Cities with Various Diphtheria Death Rates*

	40 and Over	20 and Over	10 and Over	Under 10
1890-1894	50	50	52	2
1895-1899	33	49	56	0
1900-1904	18	43	55	1
1905-1909	2	36	55	3
1910-1914	1	34	53	13
1915-1919	0	22	52	18
1920-1924	0	13	52	18
1925	0	4	28	49

It is evident from a comparison of the summaries that annual variations in diphtheria mortality are quite great. Of the ten cities with the highest rate in 1924 (table 9), only three—Denver, Camden and Minneapolis—appear in the similar list for 1925, and only four of the ten lowest cities appear on the "lowest" list for both years (table 10).

TABLE 13.—*Total Average Diphtheria Death Rate, 1923-1925*

	Total Population (70 Cities)* Estimated by the U. S. Census Bureau Methods	Diphtheria Deaths	Diphtheria Death Rate per 100,000
1923	29,243,128	3,838	13.12
1924	29,810,993	3,285	11.05
1925	31,049,595	3,024	9.74

* Seven cities are omitted from this summary because data for the full period are not available

Tables 12 and 13 show impressively the waning of diphtheria as a cause of death. In 1925 for the first time there were more cities with rates under 10 than with rates over 10.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(*Continued from page 951*)

PILLS

Though the word pill is derived from *pila,* a ball, it seems best to define the word, for the purposes of practical therapeutics, as rather slowly disintegrating medicinal masses of a size and shape convenient for swallowing. They should not weigh more than 0.5 Gm., or less than 0.05 Gm. If the pill is of a larger size it is called a bolus, the use of which is at present almost entirely restricted to veterinary practice, many people almost think it an insult to have a very large pill prescribed for them. Very small pills weighing less than 0.05 and more than 0.02 Gm. are called "granules." If the weight is below 0.02 Gm., they are usually designated as "parvules." While, as a general proposition, as small a pill as possible should be prescribed, it is rarely necessary to descend to the size of granules or parvules, excepting when the attempt is made to have a child swallow a pill.

The object of giving substances in pill form is to get a definite dose in compact and almost tasteless form, and to delay somewhat the rapidity with which it develops its action. They were the most popular solid dosage form before the days of the capsule. Their main characteristic from the present day standpoint is slowness of solution and hence delay in action, so that substances which are intended to act at once should never be prescribed in pill form. On the other hand, pills are especially valuable when action on the intestine is desired or slower absorption and, therefore, gentler and more prolonged action is aimed at. Sometimes pills fail to act on account of insolubility; and it has happened occasionally that pills were found in the stools practically unchanged. This is especially liable to occur in the case of very old pills, or of compressed pills, containing much insoluble material. Pills, like capsules, must not, of course, be prescribed for little children, as it is impossible to get them to swallow these. Indeed, there are some adults who believe they cannot swallow pills. For this reason it is generally best, before prescribing pills or capsules, to ask the patient whether he can swallow them. If he thinks he cannot, it may still be policy to prescribe an encapsulated powder; to teach the patient how to swallow pills, and to advise him, if he fails, to open the capsule and take the powder.

---

* This is the fourteenth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

Official Pills.—A number of pills are official. The average dose of these is one or two pills excepting in the case of pills of phosphorus, the average dose of which is only one pill.

It will be noted that the majority of the official pills are cathartic. By reason of their slow disintegration and tastelessness, pills are an ideal method of administration for action on the bowel. In the choice among these cathartic pills, those of aloe, it seems, deserve first place. The "A. S. and B. pills" have only their small size especially to recommend them. The addition of strychnine and atropine is of no advantage because these agents are rapidly eliminated, while aloe is slow in action; hence, by the time the aloe acts, the others have long since left the system. The combination of aloe and podophyllum in "Janeway's pills" is probably rational by combining the effect of podophyllum on the small intestine with the effect of aloe on the large intestine. When the most powerful cathartic pill is required, the vegetable cathartic pill should be preferred to the compound pills of mild mercurous chloride (formerly compound cathartic pills), unless the action of calomel is especially desired. By changing the name of the compound cathartic pills, the Revision Committee of the Pharmacopeia has probably struck a blow against the popularity of this pill, but at the same time rendered humanity a service by protecting it against the danger of mercurialism from abuse of these pills due to ignorance of their composition.

Composition of Pills

	Composition, Each Pill	Gm.
Pills of aloe	Aloe	0.13
	Soap	0.13
Pills of asafetida	Asafetida	0.20
	Soap	0.06
Pills of ferrous carbonate (Blaud's pills),	Ferrous carbonate	0.06
Compound pills of mild mercurous chloride, formerly known as "compound cathartic pills,"	Compound extract of colocynth	0.08
	Mild mercurous chloride	0.06
	Resin of jalap	0.02
	Gamboge	0.015
Pills of phosphorus	Phosphorus	0.0006
National Formulary cathartic pills in increasing order of potency:		
Pills of aloin, strychnine and belladonna (A. S. and B. pills),	Aloin	0.013
	Strychnine	0.0005
	Extract of belladonna	0.008
Compound pills of aloe and podophyllum (Janeway's pills)	Aloe	0.065
	Resin of podophyllum	0.032
	Extract of belladonna	0.016
	Extract of nux vomica	0.016
Vegetable cathartic pills	Compound extract of colocynth	0.060
	Extract of hyoscyamus	0.030
	Resin of jalap	0.020
	Extract of leptandra	0.015
	Resin of podophyllum	0.015
	Oil of peppermint	0.008

The Pharmacopeia also recognizes the following two pill masses, from which pills of any desired size may be ordered. The usual dose of these masses is 0.25 Gm. Mass of ferrous carbonate (Vallet's mass), containing 35 per cent of ferrous carbonate; mass of mercury (blue mass), containing 33 per cent of mercury.

Extemporaneous Pills.—Any one of the official pills may be prescribed by merely writing the official name and stating the number of pills the pharmacist is to dispense. Pills made from official masses are prescribed by specifying the name of the mass and the total quantity, to be divided into the desired number of pills. The quantity required is obtained by multiplying the dose wanted with the total number of pills. If it is desired to prescribe a pill combination that is not found in the Pharmacopeia, it will be necessary, of course, to name each ingredient and its quantity. Such a combination is known as "extemporaneous" in contradistinction to the official pills or masses (the word extemporaneous being derived from the Latin *ex tempore,* literally, "out of time," meaning proceeding from the impulse of the moment. This word is applied not only to pills but also to all other formulas written by the physician to meet the peculiar requirements of an individual patient at the time of writing).

The need for the extemporaneous prescribing of pills might be illustrated by a brief study of so-called tonic pills, generally composed of combinations of iron, quinine, strychnine and arsenic. The elixir of iron, quinine and strychnine probably owes its popularity to its pretty greenish color and the fact that physicians generally do not taste their own medicine. The excuse that this bitter dose is given for its appetizing action cannot be advanced, because it is generally given after meals; and bitters, to be appetizing, must be given before meals. Likewise, required speed of action, secured by administration in liquid dosage form, cannot be cited in extenuation, for prolonged and continuous action rather than intense and sudden effect is aimed at. Then, why inflict such nasty, bitter stuff on a patient when we have in pill administration a method of sparing the palate and securing the same result? These pills should be prescribed extemporaneously because not every patient who feels "run down" needs iron.

If we desire, therefore, to employ iron as a tonic for a patient showing secondary anemia, we have in reduced iron, in 0.05 Gm. doses, iron pure and concentrated. Strychnine should be used sparingly or not at all when there is greatly exaggerated reflex excitability. When it is prescribed, strychnine nitrate should be preferred to strychnine sulphate, because the former is stable in the air, while the latter is not; and its average dose of 0.002 Gm., rather than a probably ineffectual dose of a half or a fourth of that amount, should be employed. It is a fact, observed clinically, that suitable patients while using such "tonics," appropriately compounded, often eat better, feel better, and gain weight. Their action probably depends on the stimulation of gastro-enteric function by the arsenic (trioxide dose, 0.002 Gm.), of neuromuscular action by the strychnine—acting directly as well as possibly indirectly by its increasing the secretion of epinephrine—and maybe on some subtle influence on metabolism exerted by the arsenic and the quinine. The latter may well be prescribed in larger dose than is ordinarily employed (0.12 Gm. or more, instead of 0.06 Gm.) if the patient's pulse is rapid and he suffers from palpitation, so as to secure the heart sedative effect of the quinine. Here, again, prescribing in each unit half the dose aimed at is good practice, thus providing against possible idiosyncrasy, and giving the direction that, if no effect is noted within three days, to double the dose. Individualization is here, as elsewhere, the price of efficient medication; and correct technic decides whether the patient will give a slowly acting medicine a chance by taking it faithfully or have a partially used bottle standing about in the house as a reproach to its prescriber.

(To be continued)

HOSPITAL SERVICE IN THE UNITED STATES

FIFTH PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The figures and data presented in this issue of THE JOURNAL will be best understood as belonging in three groups: (*a*) a complete census of all the hospital facilities of the United States, however owned and controlled, and for whatever type of patient; (*b*) a special study and a list of those hospitals that are intended for the accommodation of people in the communities in which they are located and as a matter of convenience designated as hospitals for community use, and (*c*) hospitals approved for the training of interns and those approved for residencies in specialties.

Percentage of beds in use				66			94	..		80 7			62			78		
Population per bed			386			332	..	..	2,310			960			141			

Population given in column one is according to estimate for 1925 by the United States Bureau of the Census, except for Florida, Iowa, Kansas, Massachusetts, New York, Rhode Island, South Dakota and Wyoming, which took a state census in 1925 The number of beds and the average beds in use throughout the table are exclusive of bassinets, the number of which is given for each state in the column at the extreme right

Statistics on other types of hospitals are included in table 8, page 1014, giving number, capacity, average beds in use and other data

The hospitals of the Possessions of the United States, from which it was impossible to obtain complete data in time for this article, number as follows.

Alaska, 29 hospitals, 594 beds
Canal Zone, 11 hospitals, 2 904 beds
Hawaii, 47 hospitals, 3,210 beds.
Philippine Islands, 68 hospitals, 10,072 beds
Porto Rico, 42 hospitals, 2,226 beds
Total, 197 hospitals, 19,006 beds

There are in the United States at present a total of 6,896 hospitals of all types and kinds with 802,065 beds, constantly caring for an average of 629,362 patients. The hospital departments of institutions to the number of 607, with 23,807 hospital beds and an average of 13,404 patients, are included in the foregoing figures. In addition to the total capacity just given there are 34,511 bassinets or baby cribs, making a grand total capacity for patients, including new-born infants, of 836,576. The average number of bassinets occupied is not known, but to leave them out of the count for the time being, we find that 66 per cent of all the hospital beds in the United States are constantly filled, as compared with 67 per cent for 1920 and 64 per cent in 1923.

THE 1925 CENSUS OF HOSPITALS

In making this 1925 census, the hospitals of less than five beds capacity were not counted. In regard to the 607 hospital departments of institutions, only the beds were counted that are actually used in caring for the sick, omitting entirely all that large unknown number of beds used for custodial purposes. The various data are given by states wherever such information is believed to be of value; for comparison, the corresponding figures are given for 1920 and 1925, respectively. Whenever population figures are referred to, the 1925 estimate of the U. S. Bureau of the Census at Washington are used except in Florida, Iowa, Kansas, Massachusetts, New York, Rhode Island, South Dakota and Wyoming, in which actual returns of state censuses taken in 1925 are used.

Table 2.—*Counties With and Without Hospitals for Community Use*

The ratio of beds to population, found by dividing the total capacity (exclusive of bassinets) of 802,065 into the population of the United States for 1925, 113,493,720, gives a ratio of one bed to 141.5 inhabitants. This, of course, is merely a gross average, and further details regarding the ratio of beds to population in different states and districts and for different types of hospitals will be found elsewhere in this article.

The five states having the largest hospital facilities are: New York, with 630 hospitals and 115,128 beds; Pennsylvania, 416 hospitals, 64,884 beds; Illinois, 380 hospitals, 54,960 beds; California, 490 hospitals, 47,328 beds, and Massachusetts, with 305 hospitals and 45,302 beds. At the other end of the scale, the states that require the least hospital facilities are: Nevada, with 25 hospitals and 913 beds; Delaware, 15 hospitals, 1,421 beds, and Wyoming, with 37 hospitals and 2,165 beds.

The ratio of beds to population in New York is one to 96.9; Pennsylvania, 143.6; Illinois, 126.7; California, 84.9; Massachusetts, 91.7; Nevada, 84.7, Delaware, 165, and Wyoming, 102.4.

THE UNIVERSAL SERVICE OF GENERAL HOSPITALS

While the number and capacity of hospitals for nervous and mental patients is impressive, if indeed not startling, a moment's reflection tells us that those figures are supplied in the main by the large state insane asylums and other large institutions used in a large degree for custodial purposes, and that by far the great majority of all kinds of acute medical and surgical work is done in that large group known as general hospitals which, though averaging smaller in size, are distributed all over the country, as will be seen on the maps illustrating this issue, to the number of 4,041 general hospitals containing 293,301 beds, 193,743, or 66 per cent of which, are occupied all the time. While the importance of special hospitals accounted for in this survey is in no sense minimized and their number is increasing, especially in the large metropolitan centers, yet it appears that the large bulk of the practice of the so-called medical specialties takes place in the general hospitals. Accurate figures are not obtainable on the number of beds and number of patients in each of the several specialties in the general hospitals, since the large majority of them do not have the services very definitely divided, it being much more economical to let the supply of beds be flexible rather than to have a certain number of beds set aside for certain types of cases. To illustrate, the number of maternity cases cared for in the general hospitals is not known, but we do know that the 220 maternity hospitals with their 6,248 beds care for an average of 4,019 patients, not including the new-born infants. We know that these maternity hospitals have a total of 3,366 bassinets; and since we may assume that the remaining 31,145 bassinets are almost wholly in the general hospitals, it is seen, judging by this rather reliable criterion, that only a little more than a tenth of the obstetric work of hospitals is done in maternity hospitals, and nearly nine tenths mainly in the maternity departments of the general hospitals.

A graphic idea of the distribution of general hospitals is gained by glancing at the maps that illustrate this issue, symbols being used to indicate types of hospitals and showing which hospitals have been established in the last five years. It is especially worth while to notice the open white symbols showing the numerous instances in which general hospitals have been built in rural sections or small towns, where previously there was not a hospital for many miles.

HOSPITALS FOR THE NERVOUS AND MENTAL

In point of capacity, the 589 hospitals for nervous and mental patients, with a total capacity of 341,480 beds, loom extremely large. The fact that 94 per cent of these beds are filled all the time, with a total of 322,342 patients ranging all the way from mild cases to the more serious and hopeless ones, might indeed be contemplated with a degree of alarm. Of course, it is well known that the 322,342 nervous and mental patients in institutions is only a part of the large number of people suffering from that type of ailment. From an economic point of view, this group of sufferers means large public expense. Since the cases are mainly chronic and the patients therefore indigent, the bulk of their care devolves on the state and indirectly on the people at large.

There are one or more institutions maintained in practically every state for those who are not in position to take advantage of the care and treatment in the smaller sanatoriums under private control, of which there are a large number. The plan used by the majority of states has been to care for this type of patients in large institutions running into hundreds and even thousands of beds in capacity. In one or two states, the policy has been to have more but smaller institutions. In Wisconsin there are forty-seven hospitals for the nervous and mental and they are maintained by counties. New York heads the list of states, with sixty institutions having a total of 52,355 beds and 50,486 patients; Wisconsin, forty-seven institutions, 11,167 beds and 10,279 patients; Pennsylvania, forty-four institutions having 26,345 beds and 25,312 patients, and Massachusetts, thirty-six institutions having 21,494 beds and 20,671 patients

These figures should be contrasted with the states of small population like Nevada with one state nervous and mental hospital having 300 beds and only 222 patients; New Mexico, one with 492 beds and 457 patients, or Delaware with two, having 750 beds and 626 patients.

TUBERCULOSIS HOSPITALS

While the sufferers from nervous and mental ailments are nearly evenly distributed over the entire United States in a certain ratio to the entire population, those suffering from tuberculosis are distributed much more according to climate

In this connection, a glance at the figures relative to tuberculous patients in different states shows at once the contrast, there being, for example, in the state of Colorado, with its population of 1,019,286, a total average of 1,475 patients, or one for each 691 of population; Arizona, with a population of 407,702, a total average of 348 patients, one to each 1,171 of population; California, with a population of 4,021,320, a total average of 2,219 patients, one to each 1,812 of population.

Contrasted with these figures are such states as Florida, which reports only one tuberculosis sanatorium, with an average of twenty-two patients, population, 1,263,549, one to each 57,434; and South Dakota, having only one institution, with an average of eighty-eight patients, and a population, 681,260; or one tuberculous patient to 7,741 population.

Along with better understanding of how to handle tuberculosis there is an increasing tendency to care for such patients in practically whatever locality the patient may live, rather than to move him to those localities which heretofore have had unwarranted reputation for beneficial effects It might be remarked in passing that many patients, particularly those who delayed the move too long, have found their long trip to the Southwest a vain one, and in too many instances have become a public charge on the already overburdened citizens of that community In some instances as high as 55 per cent of the total taxes of certain localities in the Southwest has gone to the care of hopelessly stranded tuberculous patients who have come in from other parts, seeking in vain for health.

An outstanding and commendable movement on the part of hospitals at the present time is that for the care of tuberculous patients in general hospitals. This movement promises considerable relief from both a medical and an economical point of view, and will doubtless increase to much larger proportions as rapidly as the general hospitals and the public come to realize the safety with which those afflicted with tuberculosis can be cared for in general hospitals when the proper precautions are understood and observed.

HOSPITALS FOR COMMUNITY USE

The accompanying list of hospitals for community use omits the state and other institutions that are devoted largely to the custodial care of incurable nervous or insane patients; hospitals limited to government beneficiaries, and the hospital departments of institutions for the deaf, blind and crippled and aged persons and prison hospitals. Hospitals of less than ten beds are not named, but the number of them is given at the end of the list for each state

TABLE 3—*Counties With and Without Hospitals Comparing 1920 and 1925*

Totals	3,027	3,069	1,332	1,715	1,695	1,354	56.0	44.0

Several hospitals that are reputed to be flagrantly unethical or to be harboring immoral or unqualified practitioners have been omitted from the list

The majority of the hospitals listed are general medical and surgical organizations, including hospitals for the treatment of tuberculosis, nervous and mental, and hospitals designated as maternity, orthopedic and pediatric. Those marked with a star (*) are approved by the Council on Medical Education and Hospitals for internships or the fifth year in medicine. Those that are approved for residencies for graduates who have already had a general internship are marked with a dagger (†).

All states	3,069	56 0	44.0	340	291	67	69

This list is intended solely as an inventory of community hospital resources rather than a complete list of all institutions. It accounts for a total of 4,967 hospitals, including 189 of less than ten beds capacity. The total beds amount to 388,890, the average number in use being 269,494. Bassinets were not counted as beds (table 1).

The ratio of beds to population varies greatly with communities, as will be seen by reference to table 4, showing, for example, in the District of Columbia an effective supply of hospital beds at the rate of one for each 58 persons; Nevada, one for each 154 persons, and California, one for each 174 persons. Contrast with these the situation of South Carolina, where one bed must suffice for 797 persons; Mississippi, 778, and Oklahoma 736.

The average number of patients in these hospitals for community use is 69 per cent of the capacity, as compared with 67 per cent in 1920; also during the last five years there has been an increase in this kind of hospital service from 4,013 to 4,967 hospitals and from 311,159 to 388,890 hospital beds. Increases and decreases in hospitals of all types are shown in table 8.

The accompanying tables indicate that in certain states, even where the number of hospital beds is low in proportion to population, there is still a large percentage of the hospital beds unused. The largest percentage of idle beds appears to be in Delaware, where only 50 per cent of the beds are in use; next comes Arkansas with 51 per cent and Idaho, Montana, New Mexico and

Oklahoma, each 52 per cent. States representing the highest percentage of beds in use are: District of Columbia, 83 per cent; Maryland, 78 per cent; Missouri, Pennsylvania and Vermont, 75 per cent.

The encouraging progress that is undoubtedly being made all over the United States in placing hospitals in districts that have heretofore been entirely without them is indicated on the maps, particularly by the open white symbols indicating where hospitals have been opened within the last five years.

PHYSICIANS CONNECTED WITH HOSPITALS

In connection with the 1925 census of hospitals, each institution was asked to send in a list of the physicians on its staff, also separate lists of resident physicians and of interns, and to indicate whether the superintendent or administrative head is a physician. The total number of physicians connected with hospitals, as reported on all these lists, is 94,124, and they are distributed as follows: staff, 79,621; resident physicians, 5,945; superintendents, 2,648, and interns, 5,910. In making this count it has not been possible to eliminate duplicates, of which there are many, because of individual physicians serving on more than one staff. On the other hand, no estimate is offered for those hospitals that failed to turn in their staff lists. There are 3,290 physicians on the paid staffs of 485 state, federal and national government hospitals, 433 being in New York State alone; 245 in Maryland; 237 in Pennsylvania; 197 in California, and 181 in Illinois. The 4,138 civilian hospitals that sent in staff lists had a total of 76,331 physicians on their staffs. The largest number of physicians accommodated in civilian hospitals in each of the largest states are as follows: New York, 12,350; Pennsylvania, 5,710; Illinois, 4,844, and Massachusetts, 4,513. There are 5,945 resident physicians hired by 2,552 hospitals. Six hundred and twenty-two state and federal hospitals employ 2,548 resident physicians, and 1,930 civilian hospitals have a total of 3,397 resident physicians.

PHYSICIANS AS HOSPITAL ADMINISTRATORS

Without arguing the question as to whether a medically trained man is to be preferred as a hospital superintendent, it seems quite certain that the number of such superintendents has not increased in the last two or three years. In all the 6,896 hospitals in the United States at the present time, 2,648 are administered by physicians, as compared with 2,668 in 1923. On the other hand, the number of registered nurses acting as superintendents has increased from 1,283 in 1923 to 1,676 in 1925. Superintendents having neither the M.D. nor the R.N. degree numbered 2,810 in 1923 and

Three General Hospitals of less than 10 beds	19	17
Total for community use, 24	767	429

In Wyoming the following seven counties have no hospitals for community use: Campbell, Crook, Johnson, Niobrara, Sublette, Uinta, Weston.

GRAND TOTALS

	Total Beds	Av. Beds in Use
One hundred and eighty-nine General Hospitals of less than 10 beds	1,330	636
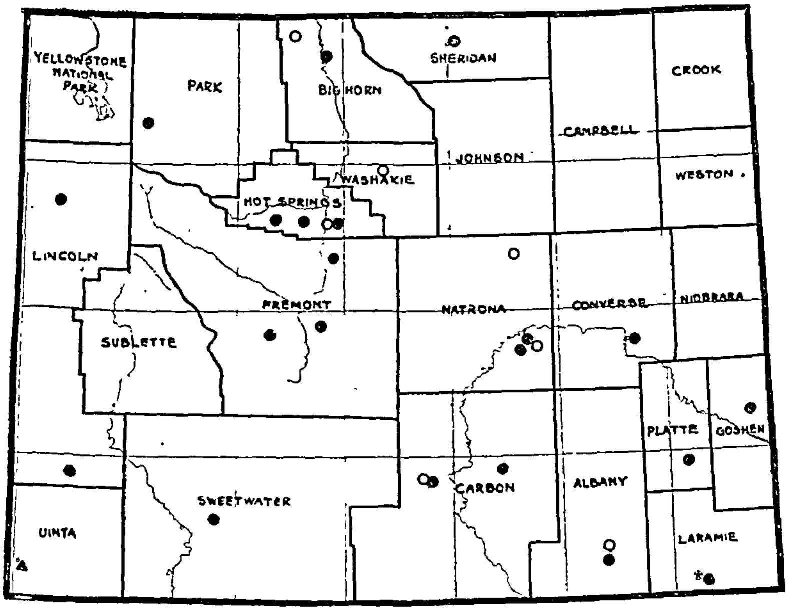
For community use, 4,967	388,890	269,494

WYOMING



● Hospital for community use. ▲ Nervous and Mental Hospital.
✚ Tuberculosis Hospital. ○ ✜ △ Established since 1920.

Total hospitals in Wyoming, 37; for community use, 24; population per hospital bed, 289; percentage of beds occupied, 55; percentage of counties without hospitals, 31.8.

HOSPITALS APPROVED FOR INTERNSHIPS

By the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago

Revised to April 3, 1926

The following general hospitals containing 149,221 beds are considered in position to furnish acceptable internships for medical graduates. For approved graduate medical schools, also hospitals providing approved residencies in certain specialties, send 10 cents for list.

HOSPITALS, 553; INTERNSHIPS, 4,724

St. Mary's, Colonial, Kahler, Worrell and Damon Hospitals, Rochester, Minn.—Services in these hospitals form part of the Fellowships in the University of Minnesota Graduate Medical School. See Jr A. M. A., April 16, 1924, pp 520.

Wills Hospital, Philadelphia.—Residencies, 16 Months, in Ophthalmology. Mr Stephen Wierzbichi, Superintendent

Paris—International Clinics of
Facio Maxillary Surgery, St Lo
Courses in Oto Rhino Laryngology a
inquiries may be addressed to Dr. J. Eastman Sheehan, 636 Fifth Ave., New York.

Porto Rico—Presbyterian Hospital, San Juan.—Courses in Tropical Medicine. Dr. Garry R. Burke, Associate Medical Director.

Future Additions to the Approved Lists

Hospitals that want to be accredited for interns and also those special or general hospitals which provide residencies or advanced internships in specialties are invited to make application to be included in the appropriate list. Approval of residencies in specialties is extended to only those hospitals that require a general internship for admission to the residencies. The requirements for approval under either list are available in pamphlet form.

A PRACTICAL PLAN FOR CHECKING AND RECORDING THE WORK OF INTERNS

With the increasing importance of the fifth, or intern, year in hospitals there is a demand for some practical scheme for recording and checking the work of the interns to insure that they go through a sufficient amount and variety of medical and surgical procedures.

The scheme that is described here is one that is in use by the Leland Stanford University in checking the work of the interns. It consists of a list of the procedures required to be performed by the interns in the course of their internship in the Lane Hospital, San Francisco, and also cards similar to the one illustrated in this article. "The outline of procedure does not include the ordinary work-up and therapy of the intern's cases, but consists of procedures which were found from questioning recent graduates to be most useful in starting general practice. The outlining of these practical points in therapy not only helps the intern to make a living in competition with the older practitioners, but, in addition, checks his work in the hospital so that the essential points are not overlooked in the hurry of a big service. This makes the institution realize that the intern has certain things to learn and that it is the duty of the organization to see that he gets them"

PROCEDURES REQUIRED TO BE PERFORMED BY STUDENT INTERNS IN THE COURSE OF THEIR ROTATING INTERNSHIP AT THE LANE HOSPITAL, SAN FRANCISCO

A. Medicine
  1. Enemas—colonic flushes—proctoclysis.
    Thoracentesis.
    Intravenous injections
    Transfusions.
    Removing stomach contents, washing stomach.
    Laboratory work
    Vaccinations
  2. Neurology and psychiatry:
    Nasal feeding
    Packs
    Lumbar puncture
    Intraspinal treatments
  3. Pediatrics:
    Technic of nasal and mouth gavage and lavage
    Intramuscular injections
    Intravenous injections
    Intraperitoneal injections
    Spinal punctures
    Skin tests—tuberculin and Schick and protein test.
    Hypodermoclysis.
    Bladder catheterization of infants and children.
    Infant feeding—normal and pathologic.
B. Surgery:
  1. Minor surgery:
    Boils
    Carbuncles.
    Sebaceous cysts.
    Felons.
    Paronychiae.
    Fractures (under supervision).
    Herniotomy.
    Appendectomy.
    Hemorrhoidectomy.
    Anesthetics.
  2. Orthopedics:
    Plaster dressings.
    Splints
    Physiotherapy.
    Heat.
      Baking
    Electricity.
      Galvanism
      Faradism
      Sinusoidal current.
      High frequency.
      Static.
    Hydrotherapy.
      Douche—the Scotch douche.
      Whirlpool baths
      Contrast baths.
      Local compresses
  3. Genito urinary
    Treatment of acute gonorrheal urethritis.
    Treatment of chronic urethritis.
    Anterior and posterior urethral and bladder.
    Irrigations, passing sounds, prostatic massage.
    Urethral calibration.
    Passing catheters.
    Adult circumcision.
  4. Nose and throat.
    Diagnostic puncture and washing antrum.
    Control of nasal hemorrhage
    Tonsillectomy.
    Adenoidectomy
    Paracentesis of membrana tympani.
  5. Eye:
    Treatment of conjunctivitis.
    Treatment of trachoma
    Treatment of glaucoma
    Treatment of iridocyclitis
    Treatment of chalazion
  6. Gynecology and obstetrics:
    Deliveries
    Perineorrhaphies.
    Trachelorrhaphies
    Episiotomies.
    Low forceps.
    Circumcision of infants.
    Curettages
    Closures
    Fitting pessaries.
    Cauterization of Skene's glands.
    Cauterization of cervices.
    Patency test of tubes.
    Packing a uterus for bleeding.
    Anesthetics (obstetric gas).
    Laparotomies—incisions.
    Appendectomy.

The foregoing outline of procedures and the sample card are published, not as standards for universal adoption, but because it is believed that they are suggestive. Others who have worked out plans that they are using are invited to send in their suggestions to the Council on Medical Education and Hospitals.

REPORT ON CLINICAL LABORATORY SERVICE IN THE UNITED STATES

A. PRELIMINARY STEPS[1]

At the San Francisco session of the American Medical Association, June, 1923, the House of Delegates referred to the Bureau of Legal Medicine and Legislation, with power to act, a resolution authorizing the President to appoint a committee to confer with representatives of the American Chemical Society and the American Association of Pathologists and Bacteriologists, and to report one year later with recommendations. Subsequently, the House of Delegates, on the initiative of the Section on Pathology and Physiology, authorized the President to appoint a committee "to undertake an investigation of clinical laboratories with a view to securing a responsible and proper supervision of and adequate equipment and facilities for this branch of medical work." The President referred the matter to the Council on Medical Education and Hospitals, which appointed a special committee consisting of Dr. Louis B. Wilson, chairman, and Drs. Francis C. Wood, E. R. Stitt, C. P. Emerson and D. J. Davis. On the initiative of the Bureau of Legal Medicine and Legislation, the American Chemical Society appointed, as its committee, Dr. Julius Stieglitz, chairman, and Drs. C. L. Parsons and Charles H. LaWall, while the American Association of Pathologists and Bacteriologists appointed Dr. O. T. Schultz, chairman, and Drs. Arthur I. Kendall, D. J. Davis, J. P. Simonds and E. R. LeCount.

The three committees met jointly at the headquarters of the American Medical Association, March 6, 1924, with Dr. W. C. Woodward, secretary of the Bureau of Legal Medicine and Legislation, who was selected to act as chairman, and Dr. Paul N. Leech, director of the chemical laboratory, who acted as secretary without vote.

After a full discussion of those aspects of laboratory control of interest to the medical profession and to nonmedical men belonging to other professional groups, the joint committee defined the term "clinical laboratory," as used by the committee, as "an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, progress and source of disease." Also it was the unanimous judgment of the joint committee that:

1. It should be illegal for any person not licensed by law so to do, to assume the responsibility of making the diagnosis or of deciding on the progress or source of disease on the basis of any results of a chemical, pathologic, serologic, bacteriologic, radiologic or microscopic observation or other laboratory examinations undertaken; and where laws do not now restrict diagnosis or the clinical interpretation of laboratory examinations to licensed classes of medical practitioners, laws should be enacted to effect that end.

2. Any law providing for the licensing of professional workers in laboratories devoted to ascertaining the presence, progress or source of disease should provide for the examination of members of each profession by competent authorities belonging to the same profession.

3. As long as an organization or individual engaged in examinations to ascertain the presence, source or progress of disease refrains from all diagnostic and prognostic interpretation of the results of such laboratory tests as provided for in paragraph 1, any effort to force such organization or individual to place itself under the direction of a representative of any other profession is to be deprecated.

4. The American Chemical Society, the American Medical Association and the American Association of Pathologists and Bacteriologists should cooperate to establish the principles enumerated in the foregoing resolution whenever legislation in this field may be proposed, and the cooperation of other national bodies should be solicited.

5. Clinical laboratories should be standardized in accordance with the principles laid down in the preceding paragraphs, and legislation should be enacted to insure competent personnel and suitable equipment.

Further, the joint committee decided that it was the sole province of the committee appointed by the American Medical Association to undertake the contemplated survey of clinical laboratories.

The report of the joint committee was approved by the council of the American Chemical Society and the council of the American Association of Pathologists and Bacteriologists, and on June 11, 1924, it was approved by the House of Delegates of the American Medical Association at the Chicago session. At the same session the committee of the American Medical Association, having been assigned the duty of making the survey, passed on to the Council on Medical Education and Hospitals the duty of making the survey, the replies to which were to be "properly analyzed and be made a part of the criteria for determining the standard of any list of approved laboratories, the making or publication of which the Council may recommend." The committee further recommended to the Council on Medical Education and Hospitals certain questions to be included in the survey, and those questions with others were incorporated in a brief but comprehensive questionnaire, which was drafted and submitted for suggestions to each member of the three committees named above and also to representatives of the American Association of Clinical Pathologists. With their additional questions and suggestions the questionnaire[2] was completed.

B. COOPERATION AND RESPONSE OF LABORATORIES

It also became apparent that it was advisable to confine the survey for the present to the laboratories that make a business of doing clinical work for physicians, omitting the hospital laboratories, of which there are 3,939, the public health laboratories, and the roentgen-ray and other highly specialized laboratories.

A personal letter explaining the origin and purpose of the survey was written to each of the 1,403 laboratories and concerns that were supposed to be laboratories, each letter accompanied by a questionnaire and a stamped return envelop. All that failed to answer were followed up at least twice with personally signed letters, and special appeals were also sent to them by various individuals and organizations which cooperated to secure as complete a return of the questionnaire as possible.

The Council received from the 1,403 laboratories on the mailing list a total of 1,080 replies. Eliminating nonclinical laboratories from among the 1,080, we have remaining 618 that do clinical work for physicians. Of these, there were 314 regular commercial clinical laboratories that answered practically all the questions, and those 314 complete reports were made the basis of the tabulation and of the report which follows. The incomplete reports, while not tabulated, nevertheless were useful for suggestions and data which they contained.

The greatest number of reports received from any one state was 55 from New York. Other states were as follows: Illinois, 32; California, 25; Texas, 21; Ohio, 16; Missouri, 14; Pennsylvania, 12. Among the 314 laboratories sending in complete reports, 198 are owned by individuals, 60 by partnership, and 56 are corporations. New York State reported 37 individually owned, 8 partnerships, and 10 corporations.

The answers regarding equipment were quite full, but probably the best idea of the equipment is gained from the types and amount of work that is done rather than the direct statements of the laboratories regarding their equipment (tables 1 and 2). From their reports on the kind and amount of work done, we gather the following summary regarding equipment:

---

[1] The report of the preliminary steps, including reports of committees, is found in appendix A.

[2] The full text of the questionnaire is given in appendix B.

Number of Laboratories	Equipped For
117	Tissue pathology
243	Clinical pathology
285	Serologic work
296	Blood chemistry
300	Bacteriology
118	Research
86	Roentgen-ray diagnosis
45	Roentgen-ray therapy

DIRECTORS AND OTHER PERSONNEL

Under the heading of directors and other personnel, the 314 laboratories reported a total of 338 directors, of whom 265 have the M.D. degree, forty-nine have other degrees but not M.D., and twenty-four have no degree (table 1). Answers regarding personnel other than the directors accounted for a total of 774 persons, and among this subsidiary personnel were 155 physicians and 619 others.

KINDS AND AMOUNT OF WORK DONE

The kind or type of work and the amount done was reported *in terms of the main kinds of work commonly done in the* average complete clinical laboratory, and are shown in greater detail in table 2. The total number of tests accounted for by the 314 laboratories is 2,115,016 annually, distributed as follows:

Blood	238,873
Feces	43,993
Gastric	29,001
Spinal fluid	18,673
Sputum	81,017
Urine	843,924
Vaccines	23,054
Necropsies	2,319
Bacteriologic	201,842
Serologic	68,515
Pathologic	58,185
Blood chemistry	64,311
Basal metabolism	17,295
Electrocardiograph	2,182
Wassermann	323,589
Sensitization tests	20,459
Others	77,784
Total, 314 laboratories	2,115,016

Average, 6,736 per laboratory.

QUESTIONS RELATING TO TREATMENT AND DIAGNOSIS

In answer to the question, "Does the laboratory give any *treatments?" 125 laboratories said that they do give treatments* and 189 that they do not give treatments. As to the kinds of treatments, 48 answered they give intravenous treatments; 38, vaccine; 37, roentgen ray. Still other kinds of treatments are given by 43 laboratories.

The question "What are the rules relating to diagnosis and treatment?" was intentionally so worded as to make it impossible to answer with "yes" or "no" and to draw out original statements about their policies regarding diagnosis and treatment. This question was quite freely answered, and while the replies do not admit of tabulation, the following are characteristic:

> All reports sent direct to physicians in writing.
>
> Diagnosis is given only to physician referring the case. Treatment only of cases referred by physicians, and dosage carefully measured with Furstenau intensimeter.
>
> No diagnoses given except when the reports of the findings constitute a diagnosis.
>
> Interpretation of the results of examination is left to the physician in charge of the case.
>
> Referred back to physician.
>
> Reports sent direct to the doctor in charge of the case.
>
> In some cases we suggest types of treatment.

Very similar to the question about rules relating to diagnosis and treatment are the questions: "What supervision is there over the diagnoses and treatments?" and "Is diagnosis or treatment ever made by persons not licensed to practice médicine and not working under the immediate supervision of a licensed physician?" It was stated by four laboratories that diagnoses are made by unlicensed persons who were not supervised by a licensed physician, and by 310 laboratories that such diagnoses are not made.

Coming to the question as to what contract work is done, (*a*) for medical institutions, and (*b*) for nonmedical organizations, sixty laboratories do contract work for medical institutions and twenty-nine do contract work for nonmedical institutions; also twenty-nine stated that they do contract work for physicians. The terms of the contract were given in most of the cases, but they are not reducible to a statistical report.

RESEARCH WORK

The questionnaire asks whether the members of the staff of the laboratory are doing research work, and they are asked to state briefly the nature of this work. One hundred and thirty-six laboratories answered that research work is being carried on. Animal experimentation is being carried on in 111 laboratories.

The laboratories whose staff publish scientific papers reported that 305 such papers were put out last year.

PUBLICITY

Many of the laboratories, as requested, sent in the names of the papers, journals and periodicals in which advertisements were carried last year, and also mentioned other means of publicity that were employed. They also sent in copies of their fee lists, form letters, blotters, prospectuses, and clippings of advertisements carried during the year. The medical journals are used by 169, while only nineteen stated that they advertise in nonmedical papers. Form letters are employed by seventy laboratories.

On the question as to whether the laboratory conducts a keep-well service for the laity, twenty-seven answered that they do conduct such a service and 287 that they do not.

SOURCE OF PATRONAGE

It was reported by 242 of the 314 laboratories that all their work is received through physicians, while seventy-two stated that they received work both through physicians and direct from patients. The reports on tests are mailed direct to the physicians only, by 279 laboratories and thirty-five say that they do not mail all reports direct to physicians.

Ninety-eight laboratories report that physicians connected with the laboratory have a medical practice of their own, and 217 laboratories answered the same question in the negative.

RELATION WITH OTHER INSTITUTIONS

Two hundred and twenty-six laboratories do work for hospitals, and sixty-eight of them do work for other institutions, such as clinics. One hundred and six do some public health work for city, state or federal government.

C. PREPARATION OF A SET OF STANDARDS

As soon as the tabulation of questionnaires was completed, a digest was prepared which included the tables and other data contained in this article. A preliminary draft of the "Essentials of an Approved Clinical Laboratory" * was made, the report of the joint committee being used as a basis, containing also ideas growing out of the survey and the resulting correspondence.

Copies of the digest of survey and of the preliminary draft of the "Essentials" were submitted to all members of committees and representatives of all agencies participating in the survey and to representatives of interested organizations and members of the Council on Medical Education and Hospitals, for their criticism and suggestions. Through correspondence and conferences with the parties concerned, all the various principles and standards suggested have been fully discussed, and the principles and standards set forth in the accompanying paragraphs under the heading of "Essentials of an Approved Clinical Laboratory" have been agreed on.

---

* The text of the preliminary draft of the "Essentials" will be found on pages 1068 and 1069.

ESSENTIALS OF AN APPROVED CLINICAL LABORATORY

DEFINITION

A clinical pathologic laboratory is an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the presence, nature, source and progress of disease in the human body.

Only those clinical laboratories in which the space, equipment, finances, management, personnel and records are such as will insure honest, efficient and accurate work may expect to be listed as approved.

LOCATION, HOUSING AND EQUIPMENT

The housing and light should be adequate for the proper functioning of the laboratory. The equipment should be sufficient to permit all essential technical procedures to be properly carried out.

SCOPE

A general clinical laboratory should be prepared to render the following services:

(*a*) Hematologic: Blood counts, blood grouping and coagulation tests, and tests for blood parasites in general.

(*b*) Biochemical: Qualitative and quantitative analyses of urine, blood, gastric contents, body fluids, feces, intestinal contents and cerebrospinal fluids; renal and hepatic function tests and basal metabolism.

(*c*) Bacteriologic: Bacteriologic diagnoses; preparation of vaccines and blood and body fluid cultures.

(*d*) Serologic: Serologic diagnoses; agglutination, complement fixation, or precipitin and lysis tests.

(*e*) Pathologic: Preparation of paraffin, celloidin or frozen sections, microscopic and gross pathologic specimens and necropsies.

(*f*) Parasitologic: Protozoal and zoological diagnoses.

PERSONNEL

(*a*) *The Director.*—The director of an approved clinical laboratory in which diagnoses and prognoses are made must be a graduate of an acceptable medical college, who is in reputable standing as a physician, has specialized in clinical pathology for at least three years, is reasonably familiar with the manifestations of disease in the patient, and knows laboratory work sufficiently well to direct and supervise technical procedures and to recognize the clinical value of laboratory reports. In brief, the director of a clinical laboratory should be sufficiently qualified to receive the same recognition as other specialists in medicine. He should be on full time or have definite hours of attendance sufficient to insure proper supervision of the laboratory work.

In laboratories in which clinical tests are carried out without any attempt to make diagnostic or prognostic interpretations and laboratories in which the tests are made for physicians who will make their own diagnoses and prognoses, the director may be a doctor of public health or a doctor of philosophy who has specialized in bacteriology, pathology,

biochemistry or other allied subjects and who must be a person in good standing in his profession. In the latter institutions, however, there shall be also one member of the clinical staff who shall be charged with the duty of assisting physicians in the interpretation of the results of laboratory examinations, and this member of the staff must be a licensed graduate in medicine who has specialized in clinical pathology for at least three years and who is devoting the major part of his time to this work. The name of the director and—where the director is not a physician—of the staff physician also must appear on all reports and printed matter issued by the laboratory.

(*b*) *Assistants.*—The director should have a corps of assistants and technicians, responsible to him, and for whom he is responsible, to carry out promptly, intelligently and accurately the several kinds of service the laboratory offers. All their reports, not only of tissues but also of all bacteriologic, hematologic, biochemical, serologic and pathologic data, should be made to the director.

REPORTS

The approved clinical laboratory should make its reports through the director, if a physician; otherwise, through its staff physician, who should furnish advice concerning these reports and their diagnostic significance solely to the physician in charge of the patient. All blanks for reports and other documents should have the name of the director printed on them, and, if the director is not a physician, of the staff physician also.

RECORDS

Full records of all examinations made by the laboratory, suitably indexed and filed, are essential. Every specimen analyzed in the laboratory should be given a serial number, which should follow that specimen in the records and reports. When the laboratory report concerns a hospital patient, an exact transcript of the laboratory record should be appended to the hospital case record. Each specimen submitted to the laboratory should have appended pertinent clinical data.

LIBRARY

The laboratory should be provided with, or have convenient access to, a library including current scientific books and journals on all the various subjects required in its work.

FEES

There should be no dividing of fees or rebating between the laboratory or its director and any physician, corporate body or group.

PUBLICITY

Publicity of an approved clinical laboratory should be in professional good taste and be limited to statements of fact, as the name, address and telephone number of the laboratory; names and titles of the director and other active responsible personnel; fields of work covered; office hours; directions for sending specimens, etc., and should not contain misleading statements or claims of unusual superiority. It should not advocate medical fads nor lay undue stress on the importance of laboratory findings.

Only the names of those rendering regular service to the laboratory should appear on letterheads, or any other form of publicity as being connected with the laboratory.

Advertising matter should be directed only to physicians either through bulletins or through recognized technical journals, and never to the nonprofessional public, as, for example, by announcements in popular journals and per odicals, circulars, pamphlets, telephone lists or other mean

PROVISIONAL LIST OF CLINICAL LABORATORIES

The following list of laboratories is compiled from the large number reported which, so far as the questionnaires show, fulfil the "Essentials of an Approved Clinical Laboratory"* as prepared by the committee Undoubtedly, many laboratories that would prove acceptable if questionnaires were answered would come under this list, and at the same time there are some on the list that, on further revision, may have to be omitted

APPENDIX A.—FULL REPORT OF PRELIMINARY STEPS TO THE SURVEY OF CLINICAL LABORATORIES

I. Report of Bureau of Legal Medicine and Legislation of the American Medical Association to the House of Delegates on the Control of Clinical Laboratories.

San Francisco, June, 1923.

At the San Francisco session, the House of Delegates referred to the Bureau of Legal Medicine and Legislation, with power to act, the following resolution:

Whereas, Measures for the control of clinical laboratories have been introduced in the legislatures of certain states, and

Whereas, This form of legislation affects the interests of physicians, chemists, bacteriologists and pathologists; therefore, be it

Resolved, That the House of Delegates authorize the President to appoint a committee to confer with representatives of the American Chemical Society, and the Association of Pathologists and Bacteriologists regarding this matter and report back one year hence with such recommendations as may be pertinent; provided in the interim the Board of Trustees, cooperating with the committee, take such action as may be necessary to protect the interests of the profession and the public.

Subsequently, the House of Delegates, on the initiative of the Section on Pathology and Physiology, adopted the following resolution:

The Section on Pathology and Physiology respectfully recommends to the House of Delegates that a committee be appointed by the President to undertake an investigation of clinical laboratories with a view to secure a responsible and proper supervision of and adequate equipment and facilities for this branch of medical work.

Pursuant to this resolution, the President referred the matter to the Council on Medical Education and Hospitals, and the latter appointed a special committee as follows:

Dr. Louis B. Wilson, Chairman.
Dr. Francis C. Wood.
Dr. E. R. Stitt.
Dr. C. P. Emerson.
Dr. D. J. Davis.

On the initiative of the Bureau of Legal Medicine and Legislation, the American Chemical Society and the American Association of Pathologists and Bacteriologists appointed committees to confer with representatives of the American Medical Association. The committee appointed by the American Chemical Society was made up of:

Dr. Julius Stieglitz, chairman,
Dr. C. L. Parsons.
Dr. Charles H. LaWall.

The committee appointed by the Association of Pathologists and Bacteriologists comprised the following:

Dr. O. T. Schultz, chairman.
Dr. Arthur I. Kendall.
Dr. D. J. Davis.
Dr. J. P. Simonds.
Dr. E. R. LeCount.

The several committees named above met with Dr. Paul N. Leech of the Chemical Laboratory of the American Medical Association, who acted as secretary, without vote, and with Dr. William C. Woodward, executive secretary of the Bureau of Legal Medicine and Legislation, in the offices of the Association, March 6, 1924. Dr. Woodward was elected chairman. After a full discussion of those aspects of laboratory control of interest to the medical profession and to nonmedical men belonging to other professional groups, the resolutions set forth below were adopted. The joint committee believed that it was not its province, but rather the sole province of the committee appointed by the American Medical Association, to undertake an investigation of clinical laboratories with a view to secure a responsible and proper supervision of and adequate equipment and facilities for them, as contemplated in the second of the resolutions adopted by the House of Delegates, set forth above.

The resolutions adopted at the joint meeting are as follows:

REPORT OF JOINT COMMITTEE

In proposing the following specific recommendations concerning the regulation of clinical laboratories, the joint committee of the American Medical Association, the American Chemical Society and the American Association of Pathologists and Bacteriologists wish to emphasize the importance of encouraging and insuring the adequate education of every laboratory worker in the fundamental sciences which he applies. A clinical laboratory, as that term is used by the committee, is an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, progress and source of disease.

It is the unanimous judgment of the committee:

1. That it should be illegal for any person not licensed by law so to do, to assume the responsibility of making the diagnosis or of deciding on the progress or source of disease on the basis of any results of a *chemical, pathologic, serologic, bacteriologic, radiologic or microscopic* observation or other laboratory examinations undertaken; and that where laws do not now restrict diagnosis or the clinical interpretation of laboratory examinations to licensed classes of medical practitioners, laws should be enacted to effect that end.

2. That any law providing for the licensing of professional workers in laboratories devoted to ascertaining the presence, progress or source of disease should provide for the examination of members of each profession by competent authorities belonging to the same profession.

3. That as long as an organization or individual engaged in examinations to ascertain the presence, source or progress of disease refrains from all diagnostic and prognostic interpretation of the results of such laboratory tests as provided for in paragraph 1, any effort to force such organization or individual to place itself under the direction of a representative of any other profession is to be deprecated.

4. That the American Chemical Society, the American Medical Association, and the American Association of Pathologists and Bacteriologists should cooperate to establish the principles enumerated in the foregoing resolution whenever legislation in this field may be proposed, and that the cooperation of other national bodies should be solicited.

5. That clinical laboratories be standardized in accordance with the principles laid down in the preceding paragraphs, and legislation should be enacted to insure competent personnel and suitable equipment.

The foregoing report of the joint committee has been approved by the Council of the American Chemical Society and the Council of the American Association of Pathologists and Bacteriologists. It is recommended that it be approved by the House of Delegates.

William C. Woodward, Executive Secretary.

II. Report of Committee on the Control of Clinical Laboratories to the Council on Medical Education and Hospitals of The American Medical Association.

Chicago, June 11, 1924.

Pursuant to a resolution of the House of Delegates in June, 1923, the president of the American Medical Association appointed the committee named below to confer with representatives of the American Chemical Society, of the American Association of Pathologists and Bacteriologists, and of the Section on Pathology and Physiology of the American Medical Association concerning the control of clinical laboratories. The arrangement for the conference was referred to the Bureau of Legal Medicine and Legislation. This conference was held in Chicago, March 6, 1924. A report of the proceedings made by the Bureau of Legal Medicine and Legislation is herewith appended. In this report it is stated that:

"The joint committee believed that it was not its province, but rather the sole province of the committee appointed by the American Medical Association, to undertake an investigation of clinical laboratories with a view to secure a responsible and proper supervision of and adequate equipment and facilities for them as contemplated in the resolutions adopted by the House of Delegates set forth above."

The joint committee also defined clinical laboratory as follows:

"A clinical laboratory, as that term is used by this committee, is an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, progress and source of disease."

The paragraphs quoted above place on the committee from the American Medical Association the work of making a survey of all clinical laboratories, either within or unconnected with hospitals in the United States. If this enormous task is to be undertaken, the committee believes it can best be done through the Council on Medical Education and Hospitals acting alone or in cooperation with other national organizations interested in the same problem. The committee would therefore recommend that the Council on Medical Education and Hospitals undertake a survey of all clinical laboratories, both private and public, either within or unconnected with hospitals, which come under the definition of the joint committee as quoted above. Your committee would further recommend that the following questions be included in the Council's survey and that the replies thereto when properly analyzed be made a part of the criteria for determining the standard of any list of approved laboratories, the making or publication of which the Council may recommend.

(*a*) *Housing and Equipment.*—1. Are the housing and equipment adequate for the purposes which the laboratory purports to accomplish?

2. Are they adequate to properly serve the interests of the patients in the hospital with which the laboratory may be connected?

(*b*) *Personnel.*—1. Is there sufficient personnel for the purposes of the laboratory?

2. Are those in charge properly qualified?

3. What is the distribution of their duties?

(*c*) *Functions.*—1. What work does the laboratory purport to do?

2. Does the laboratory staff treat patients? If so, is this under the direction of the physician in charge of the patient? Is it ever done by persons not licensed to practice medicine and not working under the immediate supervision of the licensed physician?

3. What industrial work, if any, not connected with the functions of a clinical laboratory is carried on? Does such work, if any, interfere with the duties of the laboratory personnel in their clinical laboratory work?

4. Does the laboratory do contract work for nonmedical organizations? If so, what is the nature of the contract and the extent of such work?

(*d*) *Interns' Opportunities* (in hospital laboratories).—To what extent are interns required, permitted or forbidden to make routine laboratory examinations?

2. To what extent are interns required, permitted or forbidden to attend necropsies and clinical-pathologic conferences?

(*e*) *Publicity.*—1. Is the laboratory's publicity matter confined to announcements made direct to physicians either through bulletins or in recognized medical journals, or is it directed to the nonprofessional public, as, for example, by announcements in popular journals and periodicals?

2. Is its publicity in professional good taste by being limited to statements of fact, as, for example, name, address, telephone number, names and titles of active responsible personnel, fields of work covered, office hours, directions for sending specimens, etc., or does it contain misleading overstatements or claims to unusual superiority?

(*f*) *Training of Laboratory Technicians.*—Does the laboratory attempt to train technicians other than to supply the needs of its own staff? If so, are its facilities for instruction adequate and is its course of training satisfactory for the education of technicians? What certificate, if any, does it grant to technicians which it has trained?

This committee would suggest that the Council on Medical Education and Hospitals undertake at its earliest convenience, either alone or in cooperation with other national organizations, the survey of any laboratory on the foregoing plan at the request of any local unit of the American Medical Association, or of any such laboratory. It would further suggest that such a survey covering the entire United States be carried forward in a methodical manner regardless of the receipt or absence of any such requests.

Respectfully submitted.
Louis B. Wilson, Chairman.
D. J. Davis.
Francis C. Wood.

Absent from meeting, E. R. Stitt, C. P. Emerson.

APPENDIX B.—THE QUESTIONNAIRE

SURVEY OF LABORATORIES

For All Clinical Roentgen-Ray and Other Laboratories That Do Clinical Work for Physicians

Name and address......When founded.......By whom founded........

1. Type of organization: Individually owned.......Partnership........
Corporation.....Public Health [illegible] City [illegible] State [illegible] Federal......
Hospital......Group [illegible] College.....
Roentgen-Ray......O[illegible]

2. Housing: Discuss space occupied......

3. Equipment: (*a*) State in general the amount and kind of equipment...... (*b*) Is equipment adequate properly to serve the interests of the laboratory's patrons?......

4. Personnel: (*a*) Is the director a medical graduate?......If not, what degree does he hold?............ (*b*) Kindly list your staff, giving following data:

Name	Education and Degrees	Experience	Duties	Fraction of Time Spent in Laboratory
....	....	....	....	....

5. Functions: (*a*) Kindly indicate the kinds of work the laboratory purports to do. State numbers of each kind of test, approximately if necessary.

NUMBER PER YEAR

Blood... [illegible]
Electrocard[illegible]
Spinal Flui[illegible]
Pathologic.[illegible]

(*b*) Does the laboratory give any treatments?......If so, what kind of treatments are given?......

(*c*) What are the rules relating to diagnosis and treatment?..........

(*d*) What supervision is there over the diagnoses and treatments?...... By whom?......

(*e*) Is diagnosis or treatment ever made by persons not licensed to practice medicine and not working under the immediate supervision of a licensed physician?........

(*f*) What industrial work, if any, not connected with the functions of a clinical laboratory, is carried on?......

(*g*) Does such work interfere with the duties of the personnel in their clinical laboratory work?......

(*h*) Is contract work done (1) for medical institutions?......(2) for nonmedical organizations?......

(*i*) What is the nature of such work?......

(*j*) What are the terms of the contract?......

(*k*) Does the laboratory do contract work for physicians?......Is a keep-well service conducted for the laity?......

(*l*) Is all work received through other physicians or are examinations made for patients directly?......

(*m*) Are reports mailed to physicians only?......

(*n*) Do any of the physicians connected with laboratory conduct a medical practice of their own?......

(*o*) What associations do you have with hospitals?......With other institutions?......

(*p*) What public health work do you do for city, state or federal government?......

(*q*) Are the members of the laboratory staff doing research work?...... State briefly the nature of this work......

(*r*) Is any animal experimentation being carried on?......

(*s*) Give the number of papers published during the last year........

6. Publicity: (*a*) Kindly name the papers, journals and periodicals in which you have h[illegible]t year......(*b*) What other means of [illegible] Kindly send fee lists, prospectus and [illegible] carried during the last year.

7. *Training of Laboratory Technicians:* (*a*) Does the laboratory attempt to train technicians other than to supply the needs of its own staff?......(*b*) What is the length of the course?......(*c*) For whom is it intended, whether physicians, nurses, or others?..............
(*d*) Entrance requirements......(*e*) Tuition charged......(*f*) Course of instruction......(*g*) What certificate is given?......

Remarks ....

SATURDAY, APRIL 3, 1926

HOSPITAL SERVICE IN THE UNITED STATES

This week we present the fifth annual compilation of statistics regarding hospital service in the United States. Although similar statistics have been compiled and published in special bulletins since 1914 by the Council on Medical Education and Hospitals, the first regular hospital number of The Journal did not appear until in 1921, and contained statistics based on a special survey made during 1920. A hospital number of The Journal has been issued each subsequent year with the exception of 1924, when the date of issuance was advanced to early in 1925. These statistics have become more extensive as the work has progressed, and this year they are exceptionally elaborate and complete.

HOSPITALS ESTABLISHED IN FIVE YEARS

New hospitals have been established averaging about 100 each year, the total number in the five years being 508. State maps are again published similar to those in 1920. On these maps the open or white symbols indicate hospitals established since 1920. It is interesting to note in table 3, also, that of the 1,695 counties which in 1920 were without hospitals, 341 have since been supplied, leaving 1,354 which are still without hospitals.

INTERESTING DATA FOR MARYLAND

An interesting situation appears in Maryland, where the total number of hospitals has been diminished from 136 in 1920 to ninety-three in 1925. Instead of hospital facilities being lessened, however, as might be expected, on the contrary there has been an actual increase in hospital facilities, as the total number of beds has been increased by 212 since 1920, and two of the eleven counties having no hospitals in 1920 have since been supplied. Although the ratio of hospital beds to population has decreased from 1 to 231 in 1920 to 1 to 235 in 1925, nevertheless the percentage of beds constantly occupied by patients has increased from 71 per cent in 1920 to 78 per cent in 1925. It is apparent, therefore, that the hospitals discontinued have been in districts which were oversupplied, and that hospitals in districts not satisfactorily supplied have been increased in capacity. The readjustments, therefore, appear to have been of advantage.

PHYSICIANS ON HOSPITAL STAFFS

Information of special interest and importance is set forth in table 5, which gives for each state the number of physicians who at present have hospital connections, either on the staff or as residents, interns, medical directors or superintendents. The figures for staff members include some unavoidable duplications, as certain physicians are members of the staffs of two or more hospitals, especially in the larger cities. In Chicago, for example, of the 1,504 physicians on hospital staffs, there are 420 duplications, as 329 physicians are on the staffs of two hospitals each, thirty-five are staff members of three hospitals each, and seven have membership on staffs of four hospitals. It is estimated, therefore, that the total number of physicians on hospital staffs should be discounted by not more than 10 per cent, as duplications occur in the few largest cities. There are no duplications in the physicians included among resident physicians, interns or hospital superintendents. Altogether, therefore, approximately 90,000, or 60 per cent of all physicians in the United States, have immediate connection with the hospitals.

APPROVED LISTS OF HOSPITALS

Hospitals have been listed by the Council in four groups, the first three of which are approved. All hospitals named in either The Journal or the American Medical Directory are approved as places where sick or injured persons can secure at least fairly efficient care. Hospitals in which the educational function is especially developed and which provide exceptional facilities for the training of interns are included in a special list[1] of those approved for internships. A list is now being developed of hospitals which provide acceptable residencies in one or more specialties for physicians who have already completed internships in general hospitals.[2]

ELIMINATION OF THE UNFIT

The fourth group of hospitals contains the names of 294 institutions which—because of grossly unethical reasons, such as criminal practices, admission to their staffs of members who are seriously unqualified, either morally or professionally, flagrant methods of advertising or for other valid reasons—are deemed unworthy of being included in any published list of reputable hospitals. The separation of such institutions from the Council's published lists marks the development of an aggressive campaign to establish safeguards against irresponsible or malicious institutions of this type which are an actual menace to the public. For these reasons, therefore, they are excluded from the lists of institutions held out as worthy of receiving the public's patronage.

---

[1] List published on pages 1056-1063, inclusive.

[2] A tentative list of these hospitals appears on pages 1063 and 1064.

APPRECIATION

Our special acknowledgments and appreciation are extended to the many hospital superintendents, chiefs of staffs, official executives of government hospitals and many others who have cooperated with us to a most remarkable extent in the preparation of the elaborate and complete reports which have made possible the publication of these valuable statistics.

HOSPITALS MAINTAINED BY NATIONAL, STATE AND LOCAL GOVERNMENTS

The hospital services maintained by the national government have been considerably increased since 1909, largely because of conditions resulting from the World War. Of all hospital beds, the proportion controlled by the national government has increased from 2.1 per cent in 1909 to 2.3 per cent in 1914, 3.1 per cent in 1918, 6.8 per cent in 1923 and 7.1 per cent in 1925. There are now 299 hospitals maintained by the national government with a total capacity of 57,091 beds, of which an average of 42,377, or 74.2 per cent, are constantly occupied. These figures cover the hospitals maintained by the United States Army, Navy and Public Health Service, the Veterans' Bureau, and several hospitals for government beneficiaries located in the District of Columbia and elsewhere.

For many years the state governments have had a comparatively large part in the provision of hospital facilities, particularly in maintaining large hospitals for the insane, the tuberculous and sufferers from other chronic diseases. In 1909, the state governments maintained 45 per cent of all hospital beds, but by 1925 the percentage had been reduced to 40. The capacity of the 351 hospitals maintained by state governments, however, has increased from 189,049 beds in 1909 to 317,264 beds in 1925, and of the latter, 305,466 beds, or 96.2 per cent, are ordinarily occupied. To an increasing extent the states are creating and maintaining general teaching hospitals for their state university medical schools. In sixteen states, eighteen such hospitals are now being maintained with a total of 4,582 beds and an average of 3,467 patients. Ten states also maintain twenty-three general hospitals which are not essentially for teaching, these having 4,496 beds, of which 3,865 on the average are regularly occupied. Of these states, Mississippi maintains four regional charity hospitals, Louisiana has two such hospitals and Pennsylvania has ten, these being for the care of the sick and injured in the mining districts. Other states that maintain some form of general hospital service, including mainly hospitals for crippled children, are Illinois, Iowa, Minnesota, Nebraska, New York, North Carolina and Rhode Island.

Local and county governments now maintain 471 hospitals, with 53,027 beds. City governments maintain 371 hospitals with 59,630 beds, and cities and counties combined maintain sixty-nine hospitals with 7,118 beds. Altogether, county and municipal governments combined support 911 hospitals having 119,775 beds, comprising 14.9 per cent of the entire bed capacity in the United States.

At the present time, therefore, 62 per cent of all hospital beds in this country [1] are financed by government agencies—national, state, county and city. It is interesting to note that the number of beds in hospitals maintained by government agencies has held about the same ratio to the total beds in all hospitals in the country, at least since 1909, when the earliest reliable statistics were compiled regarding the bed capacity of all hospitals. This leaves 38 per cent of all hospital beds in the United States which are maintained by nongovernmental agencies.

VITAL CAPACITY AND PROGNOSIS

Vital capacity is measured by the largest expiration following the deepest inspiration. Until recently this physical feature of the respiratory functions received little serious consideration except as a physiologic experiment. Peabody has significantly remarked that those who, during the last few years, have been studying the function of respiration have devoted their attention largely to the changes in the blood gases and have paid little attention to the mechanical aspect of pulmonary ventilation. Variations in the gaseous content of the blood are of course of the utmost importance, and they affect the stimulus to respiration; but at the same time, Peabody adds, one cannot neglect the response on the part of the lungs to this stimulus. This response manifests itself in the ventilatory function of the lungs, which promotes the proper exchange of gases through the cells of the alveoli.

Since vital capacity is an indication of the competence of the mechanism of external respiration, it has of late come to be regarded as in no small degree indicative of physical fitness. For example, the measurements recently made by White and McGuire [2] of the United States Army Medical Corps on students in an army summer training camp indicate that, despite the present limitations of the technic of observation, the vital capacity is at least in some degree indicative of general physical condition. With improvement of the latter as the result of the course of training prescribed, the vital capacity tended to increase correspondingly.

As Peabody, who has devoted much attention to the subject in the clinic, recently pointed out, in medicine the determination of the vital capacity of the lungs has been most useful in the field of cardiac disease. It is less valuable in diagnosis than it is in prognosis, and it is of particular interest in following the course of cases from day to day and from week to week. According to Peabody, the graphic record of the vital capacity of the lungs in a case of chronic heart disease usually gives one a better idea of the clinical course of the case than do any of the other observations that are made. The use of the spirometer will need to be "standardized" more universally and the sources of inaccuracy or uncertainty in determinations be taken into account more adequately before the estimates will be entirely satisfactory. To one who recalls the evolution of the apparatus for the measurement of basal metabolism, such technical features do not seem forbidding. The occasionally uttered criticism that estimates of vital capacity show considerable variations in "normal" values may remind us that other valued data, such as the leukocyte counts, have helpful significance notwithstanding a considerable latitude in the deviations of the customary figures from a mean average.

---

[1] See Table 9 on page 1014.

[2] White, S. A., and McGuire, P. F.: Vital Capacity in a Citizens' Military Training Camp, Arch. Int. Med. 36: 355 (Sept.) 1925.

It is significant, therefore, that discussions of vital capacity are looming larger in the eyes of surgeons, particularly in relation to thoracic surgery. Graham of St. Louis has pointed out that the effect of various intrathoracic procedures on the mechanism of external respiration is to some extent dependent on vital capacity. Yates[3] of Milwaukee has lately defended the following theses: Estimations of vital capacity are helpful in diagnosis, in prognosis, in determining the effects of treatment and in measuring ultimate results as they record the effectiveness of the basic function, external respiration. Protection of the structures and of the activities of the structures that establish and control external respiration so that vital capacity is kept at the highest level permitted by circumstances is the guide to effective treatment of intrathoracic diseases. Deliveries of blood through bronchial arteries and through the pulmonary arteries are controlled by the functional activities of lungs, which are proportionate to vital capacities. Resistance, defense, growth and repair of intrathoracic structures, as well as of the entire organism, are commensurate with vital capacity. Accordingly, it should follow that acute and chronic intrathoracic diseases and recent thoracic injuries can be treated more simply and safely by measures that will conserve external respiration by keeping vital capacities high during active phases of maladies and leave them, after convalescence, at their highest. What procedures will best promote these desired ends may remain to be determined. When a competent surgical investigator[3] defines vital capacity as "a fair criterion of life, reaching its peak when physiologic competence is highest, diminishing as incompetence increases and becoming zero when respiration ceases," intrathoracic therapy cannot well afford to overlook this helpful index.

IRON AND BLOOD REGENERATION

"The history of anemia treatment with drugs is indeed a tale to make the judicious grieve." These are the words that Whipple and Robscheit-Robbins[1] used in discussion of their studies of blood regeneration. A multitude of drugs, they continue, have been proposed, enthusiastically supported, then questioned, and finally abandoned. On the whole, iron seems to enjoy the most constant favor by practicing physicians. Yet there are many good reasons for past and present misconceptions. Clinical control of patients is difficult and the number of variables almost infinity; therefore it need not surprise the critic to find that there have been differences of opinion relating to the influence of various drugs on various anemic conditions. Diet factors, Whipple and Robscheit-Robbins add further, are only recently coming in for proper study and consequent appreciation.

The most striking feature of this aspect of the subject is the demonstration now furnished by various investigators that iron per se is, ordinarily at least, not always the outstanding beneficial factor in the reconstruction of blood pigment. Somehow attention has been centered so many years on the uniqueness of hemoglobin as a ferruginous protein that the possible significance of the non-iron residue of the molecule tends to be overlooked. Furthermore, it is not unlikely that the degree of activity of the hematopoietic organs, whatever they are, may be quite as important as the organic and inorganic sources out of which blood is regenerated. In other words, hemoglobin formation and hematopoiesis in general are presumably complex functions the success of which is modified by various factors.

Less than four years ago, Whipple[2] specifically indicated some of these. Among the potent factors exerting a positive influence on hemoglobin, he wrote, stand, first, red meat and cooked liver, hemoglobin and butter fat. Then come spinach and full diets of common food grains and milk. Practically inert are other chlorophyl-containing vegetable leaves—celery, parsley, beet tops and sprouts. In the same negative group are fish and clams, onions and beets and animal fats, including lard and cod liver oil. Iron and arsenic in the common drug preparations are likewise inert under these conditions.[3] The inclusion of hemoglobin itself with a substance so widely different as is edible fat indicates the difficulty of interpreting the varied findings heretofore presented. To Whipple and his co-workers the value of iron seemed to depend on the severity of the anemia to be combated. Williamson,[4] who studied the problem at the University of Illinois, concluded that inorganic iron, whether given by mouth, subcutaneously or intravenously, is absorbed and may be found especially in the liver and spleen, but is not converted into hemoglobin. Animals made anemic by one or several large bleedings do not recover any more rapidly when inorganic iron is given in any of these ways. Williamson believes, however, that the efficiency of food iron is pronounced.

[3] This is discussed by Whipple, G H. Iron in Anemia, J. A M. A **86**: *367 (Jan 30) 1926*

A new complication has been injected into the current confusion by Barkan[5] of the University of Frankfort, who has conducted an inquiry into the behavior of hemoglobin toward the digestive enzymes. If the pigment itself can facilitate blood regeneration, does it do so in part by acting as a source of ionized iron? In other words, what is the fate of the iron of ferruginous compounds in the gastro-enteric tract? The new tests indicate that neither the gastric acidity nor peptic or pancreatic digestive extracts, even when used in natural sequence, liberate iron from hemoglobin. Perhaps this furnishes further significant indication that it is not so much iron as the complexes with which it is associated that determine hematopoietic efficacy. Whether such a conclusion will be further substantiated by the behavior of other potent iron-bearing organic compounds in digestion remains to be learned.

Current Comment

CLINICAL LABORATORY STATISTICS

The first presentation of statistics with regard to the clinical laboratories in the United States appears in this issue of The Journal. Measures toward the establishing of efficient supervision over clinical laboratories were initiated at the meeting of the American Medical Association in San Francisco in July, 1923. A carefully worded questionnaire was mailed to all clinical laboratories, and the statistics published are based on the replies received. Meanwhile, with the assistance and advice of the officers of the various associations interested in clinical laboratories and many other experts in laboratory work, the Council prepared a schedule of principles or essentials[6] by which a list of institutions worthy of the Council's approval could be prepared. As a result, the first tentative list[7] of laboratories deemed worthy of approval is published in this issue. In its relation to clinical laboratories, the Council's attitude is the same as that which has guided its relationship to medical colleges, graduate medical schools and hospitals. In brief, the Council makes no attempt to interfere with any clinical laboratory or to prevent it from conducting its affairs as it deems best. However, if the clinical laboratory desires to obtain the Council's endorsement as an approved institution, it should be willing to comply with the principles designated by the Council as essential in clinical laboratories which are acceptably equipped and maintained. Thus a supervision over clinical laboratories in the Unted States has been established which, it is believed, will bring results no less satisfactory than the supervision established over medical schools and hospitals.

SOME MANIFESTATIONS OF FAT EMBOLISM

Fat embolism is not a modern subject. Porter has stated that it has been studied experimentally during two and a half centuries. Interest in its pathologic manifestations has been greatly stimulated since the World War, largely because fat emboli were held responsible by some students for the manifestation of shock, illustrations of which in large numbers are furnished by combats on the battle field.[1] It is easy to produce embolism experimentally in animals when fat is injected into a vein. Liberation of fat presumably occurs after shell fracture of large bones and after multiple wounds through masses of subcutaneous fat. Porter has pointed out that the fat in bones is in a condition peculiarly favorable to its entrance into the blood vessels after fracture. Large quantities of fat have repeatedly been found in the blood vessels after fracture. The entrance of fat into the blood vessels begins immediately after the wound. Frequently, if not always, there is fat embolism of the brain and other organs. Porter looked on fat embolism of the vasomotor center as the cause of shock. That such a view has not gone without debate, the columns of The Journal have repeatedly testified.[2] Heretofore, attention has been centered largely, if not exclusively, on the occurrence of fat emboli in two groups of tissues: the pulmonary vessels and the capillaries of the central nervous system. In fact, it is the pathologic disturbance in these two regions that has been regarded above all as responsible for deaths due to fracture of the bones. Paul and Windholz[3] of Vienna have lately stated, however, that other localities may suffer from the entrance of fat in hitherto unappreciated ways. This is particularly true of the capillaries of the kidneys. The latter may become so involved that renal function is altered to the extent of inducing uremic symptoms. Thus, death may ensue in the so-called cerebral type of fat embolism not only through embolic injury to the nervous tissues but also as a consequence of direct suppression of kidney function without any likelihood of the usual nephritic degenerative changes. Liver functions may likewise be injured because of fat emboli in the hepatic capillaries. Often the manifestations of fat embolism have doubtless been misunderstood because consideration has been fixed primarily on only one or two organ groups.

DIPHTHERIA IN 1925

The annual diphtheria summary in this issue (p. 1005) affords one of the most encouraging records of recent years in preventive medicine. From 1910 to 1920, little improvement could be demonstrated in diphtheria mortality in most cities. In 1910-1914, only thirteen cities averaged rates under 10; in 1915-1919 and again in 1920-1924, there were only eighteen cities that could be so classed; but in 1924 there were thirty-seven and in 1925 forty-nine with diphtheria rates practically unknown anywhere before 1910. There can be little doubt that the amazing reduction in recent years is to be attributed in large part to the increasing immunization of school children with toxin-antitoxin mixtures or with anatoxin. This conclusion seems warranted, not only by the observations in individual cities like New York where the method has been extensively employed, but by the rapid decline in diphtheria mortality throughout the general population. In 1923, the diphtheria death rate in the large cities of the United States was 13.14; in 1924, it was 11.15, and in 1925, 9.88. Something may doubtless be credited to the curative side, since the use of antitoxin is probably more widespread and more effective each year; but the fact that since immunization measures began to be applied the diphtheria rates, previously almost stationary, have suddenly and decisively dropped indicates that the latter is the main factor. If the improvement of the last three years continues, diphtheria may well be an almost negligible factor in the mortality returns of 1930.

Association News

ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

Held in Chicago, Feb. 15, 16, 17 and 18, 1926

(Continued from page 958)

State Board of Examiners in the Basic Sciences: Wisconsin's Basic Science Law

Michael F. Guyer, Ph.D., Madison, Wis.: The design of the Wisconsin basic science law is not to render unlawful any particular mode of treatment but to insure that those who make an occupation of treating the sick shall have sufficient knowledge of the human body in health and disease to make it safe for them to do so. To prove that they have this knowledge, all candidates for license to treat the sick are required to pass examinations in the four basic sciences of human anatomy, physiology, pathology and diagnosis before they can come before their particular licensing boards. These examinations are conducted, by a board of three members, "not less than four times a year." The present board consists of two biologists and a chemist. The licensing boards are permitted, at their discretion, to accept the basic science certificate in lieu of examination in the subjects of anatomy, physiology, pathology and diagnosis. As the attorney general has ruled that chiropractors from other states are not eligible to reciprocity, the only applicants who can comply with the requirements are those who must also secure their licenses from the state board of medical examiners; hence, as regards reciprocity, the basic science board has for the time being adopted the standards of the medical board as its own. The law further states that "any person who on February 1, 1925, was regularly licensed or registered in the state of Wisconsin to treat the sick need not be registered under the basic science law." This includes not only those who were licensed to practice medicine and surgery or osteopathy and surgery, but also midwives, chiropodists and masseurs. The further specification is added that "any person who, on February 1, 1925, was not registered or licensed in the state of Wisconsin to treat the sick but nevertheless on that date was lawfully engaged in this state in treating the sick shall be registered upon presenting to the board within sixty days after this section goes into effect an application therefor with sufficient and satisfactory evidence that he was on such date lawfully engaged in this state in treating the sick, and is of good moral character, and upon the payment of a registration fee of five dollars."

DISCUSSION

Dr. John M. Dodson, Chicago: Not long before I left Wisconsin I chanced to be a member of a committee to secure the passage of an effective medical practice act. I conducted the correspondence. One interesting letter, on a sheet of legal cap paper, bore the legend at the top, "Dr. P. McGillicuddy, M.D., Physician and Surgeon, Dealer in Drugs, Medicines and Notions, also Bees and Honey." You see they were a versatile lot in Wisconsin at that time. The common sense of the present Wisconsin act appeals to the laity, and I think the lack of that feature has been one of the causes of the many failures to secure the right kind of medical practice acts and to enforce them in this country.

Dr. A. T. McCormack, Louisville, Ky.: It seems to me that we would be far better off without any laws at all than for the members of a profession to be examined by individuals who are not members of the profession. I believe firmly in an examination by a central body, but I believe that central body ought to represent the profession, and I anticipate with great alarm the time when we sign away our rights and become a profession without intelligent representation on the boards of control.

Dr. Harold Rypens, Albany, N. Y.: I do not feel that the bad thing about this law is that laymen give the examination, if they are good examiners. What I object to is that any one who comes from any eligible high school is eligible to take this examination. I look on this as a retrogression to low standard of medical licensure.

Dr. T. J. Crowe, Dallas, Texas: You are trying to get through weak and useless legislation.

J. G. Crownhart, Milwaukee: The profession in Wisconsin was not looking for something to protect the medical profession; on the contrary, it was looking for something to protect the public. This law is enacted not as a licensing measure; it is a negative measure, that you cannot go before any other board until you have passed at least this minimum requirement. It is not an attempt to bring down the standards of medical education; it is simply an attempt to protect the public from pure quackery and fraud.

Michael F. Guyer, Ph.D., Madison, Wis.: We do not license anybody or anything; we are a filter, and before anybody can come up before what may be possibly a weaker board than our medical board, like a chiropractor board, he has to pass through our hands. High school men may come before us for examination. That does not mean that we are going to pass them. We try to find out whether they know a little something about the human body and health and disease. We find many of them do not. If they do not, they cannot go before the licensing board. Suppose we did not have such a provision. They would walk over to their chiropractor board, if that was the school in which they were trained, and be licensed to practice chiropractic. As it is now, they have to go through our hands first, and while I am not an authority on chiropractic schools, the material that has come before us so far has not been material that we could pass.

Dr. Harold S. Rypens, Albany, N. Y.: After a chiropractor candidate has passed your board, what would he have to do in way of further examination and study to get his license to practice?

Michael F. Guyer, Ph.D., Madison, Wis.: He would have to pass before a chiropractic board, which is entirely a chiropractic board and distinguished from a medical board. There is a needless alarm over the lowering of standards. The whole object is to put up the standards. We have enough quacks of all kinds and various irregular cults in our own state. They have powerful lobbies back of them. You are up against the same thing. Are you going to let them swing public opinion through negligence of the medical people? The public is not educated up to what is a real, genuinely trained practitioner and what is not. Are you going to let public opinion swing over and get all sorts of licensing boards for these things or are you going to head it off somewhere?

The New Commission on Medical Education: Its Objects and Relation to Medical Licensure

Dr. Willard C. Rappleye, New Haven, Conn.: The commission is composed of three general groups: (1) those interested primarily in general and graduate education; (2) men interested in medical education proper: fundamental sciences, clinical medicine and premedical education; (3) representatives from both the National Board of Medical Examiners and the Federation of State Licensing Boards. We would be interested in knowing what are the elements of education in a basic course which prepare a man reasonably, safely and adequately to begin the practice of medicine. We are thinking of getting at the basic preparation which will prepare a person to take advantage of the new demands that will come to the medical profession in the next twenty or twenty-five years, and the new demands that come from the public. We recognize that the major problem before medicine today is not education but medical practice. We have started out to get at this question of a basic course in medicine by asking just the question, What is or what should be the general practice in medicine? We are approaching that from the needs of communities for various kinds of medical services. We are studying the actual demands that are now being made on the medical profession in the country, by getting sample experiences of men in general practice in typical communities. In medicine there are a group of questions. Among them are: What are the qualifications of individuals coming up for a medical course? What should be given in the basic course of medicine? By whom should it be given? How should it be given? A study is being made of what is happening to the 10,000-odd applicants for admission to schools of medicine when only about 4,000 are accepted.

DISCUSSION

Dr. Howard Rypens, Albany, N. Y.: I think that any legislation that is pending in the various states should be held in abeyance, if possible, until at least some of the results of this very important study have been brought before us.

Dr. Henry A. Christian, Boston: One way to study an organization and a machine is to give up studying the methods of the organization of the machine and devote our attention to a study of the product. It seems to me that one important field of this study is going to be this examination of the product. Dr. Rappleye has mentioned one very important phase of that, namely, the study of the problems that confront the physician in communities of different types, communities of different sizes, and so on, as a means of finding out in what we should instruct our students. He has touched on another phase in suggesting the great importance of getting an idea of the future development of the practice of medicine as far as you can anticipate it and preparing the man in part to meet the unexpected demand of that development. Finally, there is one phase of the thing that has always interested me. Certain schools fail to admit men each year and they never pay any attention to finding out what those men accomplish, what becomes of them. Do they keep on studying medicine? Do they go to some other school? If, so, do they succeed or do they not succeed? This survey is going to help us along those lines.

Dr. Louis B. Wilson, Rochester, Minn.: I have great faith in the board as it is constituted to arrive at a fair knowledge of the medical profession, as to what it is doing and what it ought to do, how well prepared it is and how ill prepared it is to do the work.

Dr. John M. Dodson, Chicago: It seems to me that the commission might very well consider as part of its work ways and means of educating the laity. We have framed legislation and put it on the books, but we have not convinced the public that they need it. Until we do that we might just as well not pass legislation at all. The solution of most of our ills is education of the people concerned.

(To be continued)

THE DALLAS SESSION

Multiple Reservations at Dallas

The Dallas Chamber of Commerce complains that many physicians who expect to attend the Dallas Session have made reservations at more than one hotel, and that even when notified by all the hotels concerned that such reservations have been made, none of them have been released. Such procedure is manifestly unjust and seriously complicates the hotel situation in Dallas. Of course, the hotel has to accept all requests for a reservation in good faith, and when one physician makes reservations at more than one hotel, some other physician who wishes to attend the Annual Session at Dallas has his chances for securing satisfactory accommodations reduced accordingly. All who have made more than one reservation are urgently requested to release immediately those reservations which will not be used.

Those who have not yet secured reservations at Dallas should write at once to the Dallas Chamber of Commerce. All possible effort will be made to have satisfactory accommodations for all who will attend the Annual Session.

A. M. P. O. Luncheon

Dr. Ramsey H. Moore, Medical Arts Building, Dallas, is the chairman of a committee in charge of arrangements for the annual A. M. P. O. luncheon, to be given during the annual meeting of the American Medical Association.

Motion Picture Theater

An exceedingly attractive program affords opportunity for many who come early to attend features of special interest in the Motion Picture Theater. The Motion Picture Theater opens at noon on Monday (as does also the Scientific Exhibit) and will operate also on Tuesday from 9 a. m. to 5:30 p. m., as well as on Wednesday, Thursday and Friday. Also those who wish to attend only section meetings on Wednesday, Thursday and Friday will find it an advantage to come early to the meeting in order to hear these talks on Monday and Tuesday.

Scientific Exhibit

The United States Public Health Service is actively engaged in making arrangements for the coordinating Immunologic Exhibit on vaccination. Dr. J. P. Leake is in charge and will demonstrate various types of "takes" as well as the technic of vaccination. In addition, the United States Public Health Service will have a comprehensive exhibit of its general work. The Division of Venereal Diseases will demonstrate its work, and the Division of Marine Hospitals will show the investigations in leprosy.

Wounded Prisoners of War.—The *Archives médicales belges* comments on the work accomplished by Switzerland in interchanging prisoners of war that were incapacitated by wounds or disease and interning others. The interchange arrangement allowed the return to their homes through Switzerland of 10,000 wounded French, British, Belgian or German soldiers, and in all, 75,000 soldiers were interned during the war. There were twenty different centers for the accommodation of the interned. Two Swiss committees passed on the recommendations made by the Red Cross for repatriation.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALASKA

Hospital Boat on the Yukon.—The governor of Alaska announced, March 26, that a well equipped hospital boat with a physician and two nurses on board will be put in service this year on the Yukon River and its tributaries, to minister to about 5,000 persons who would otherwise be without medical service. Most of the natives live along the banks of these streams.

CALIFORNIA

Personal.—Dr. Alexander W. Pollock, recently of Ontario, Calif., has accepted an appointment as a medical missionary to Abyssinia, to replace Dr. Thomas A. Lambie, who will return to this country on furlough. Dr. Pollock was a medical missionary in Egypt for many years.——Dr. William P. Byron has been appointed health officer of Lemoore in Kings County to succeed Dr. William F. Edmonds.——Dr. Paul E. Bowers, Los Angeles, has been elected president of the Southern California Academy of Criminology.——Dr. F. Leslie Herrick, Oakland, has been appointed assistant surgeon of the Napa State Hospital.——Dr. Francis F. Malone has been appointed health officer of Calipatria in Imperial County.

Lectures on Diseases of the Pacific Basin.—Dr. Henry S. Houghton, director of the Peking Union Medical College, Peking, China, will deliver the first course of two lectures under the Morris Herzstein lectureship on diseases of the Pacific Basin including tropical diseases, during the week beginning April 25 at Lane Hall, Stanford University School of Medicine, Sacramento Street near Webster, 8 p. m. In his first lecture Dr. Houghton will discuss the setting of western medicine in Asia and its significance in promoting international well being. The second lecture will be on nosogeography and on work that is being done in China. Physicians and all medical students are invited to attend.

Smallpox Kills 125.—In its weekly bulletin, the California State Board of Health again calls attention to the type of smallpox that prevails in the state, saying that in the first seventy days of this year, more people died of smallpox in California than during the years 1923, 1924 and 1925; between January 2 and March 13, there were 1,449 cases reported and 125 deaths. Los Angeles County suffered most; the city of Los Angeles had 636 of the cases and 108 of the deaths. The state board considers that the facts concerning the prevention of smallpox by vaccination are too well known for any individual to plead ignorance and that the responsibility for contracting smallpox now rests entirely on the individual; health officers seem to have done all that they can to encourage the continuous exercise of vaccination.

DELAWARE

University News.—Henry C. Sherman, Sc.D., professor of food chemistry, Columbia University, New York, lectured at the University of Delaware, February 16, on "Recent Advances in the Chemistry of Nutrition."

Health at Wilmington.—Telegraphic returns to the U. S. Department of Commerce from sixty-eight cities with a total population of 29,000,000, for the week ending March 6, shows that the highest mortality rate (32.5) was for Wilmington, Del., and the general mortality rate for the group of cities was 16.2; for the corresponding week of last year the mortality rate for Wilmington was 14.5, and for the group of cities as a whole, 14.6.

FLORIDA

Smallpox in Tampa.—The Tampa *Tribune* noted, March 7, that a total of 279 cases of smallpox had been reported in that city since the recent outbreak occurred, and that thirty-four of them were reported the previous week. There were then, it is said, a total of fifty-one cases in the city. There is a free vaccination clinic in the city hall. Dr. Ernest C. Levy, health officer, said that although about 50 per cent of the population of Tampa had been vaccinated, if the people do not cooperate with the health department in rounding up those who have neglected vaccination, smallpox will continue to be reported. Dr. Levy will also be head of the sanitary department by virtue of a new ordinance, which merges the health and sanitary departments under one head.

IOWA

Annual Clinic.—Physicians are invited to attend the annual clinic of the College of Medicine of the State University of Iowa at Iowa City, April 13-14; the clinic will be conducted by Dr. Campbell P. Howard, formerly professor of medicine at the state university and now at McGill University Faculty of Medicine, Montreal, and by Dr. McKim Marriott, dean and professor of pediatrics at Washington University School of Medicine, St. Louis.

Research in Cerebral Physiology.—Under the direction of Dr. Samuel T. Orton, director, Iowa Psychopathic Hospital, and head of the department of psychiatry, State University of Iowa, a two years program in research in cerebral physiology is being undertaken at the university, for which the Rockefeller Foundation has made a grant of $60,000. Two groups are at work; one, a field unit, holds psychiatric clinics in small communities to locate problem material; the other is the laboratory unit, consisting of the director and his executive assistant, an associate in neuro-anatomy and pathology, an assistant in neurophysiology, a teacher to work on methods for the corrections of disabilities, a research associate of the National Research Council, and a secretary; all of these give full time except the director. The general plan is to work on problems of "cerebral dominance" by studying cases of special disability in reading, writing and speech; to analyze the literature of cerebral anatomy and physiology, and to conduct experiments on animals.

LOUISIANA

Invitation to Visit en Route to Dallas.—The Ouachita Parish Medical Society extends a general invitation to members of the American Medical Association to attend the annual meeting of the Louisiana State Medical Society, which will be held in Monroe, April 15-17. This society will be pleased to entertain at this meeting members of the American Medical Association who are en route to Dallas.

Personal.—Dr. David A. Lines, collector of internal revenue for the department of Louisiana, has resigned, effective April 30, and will engage in the practice of medicine.——Dr. Leonard C. Chamberlain has been elected president of the clinical staff of the Presbyterian Hospital, New Orleans, succeeding Dr. Euclid J. Richard.——Dr. David E. Brown, Chatham, has accepted a position with the Louisiana State Board of Health as director of tuberculosis control.

MARYLAND

Personal.—Dr. Charles C. Hedges, U. S. public health director for Marshall County, W. Va., has accepted the position of second assistant director at the Johns Hopkins Hospital, and will be in charge of the dispensaries; he succeeds Albert W. Buck, who resigned to become director of the New Haven Hospital, New Haven, Conn.——Dr. Robert H. Riley, acting director of the state department of health, is making a study of state health work in North Carolina, South Carolina, Alabama and Tennessee.

Physician with Arctic Expedition.—Dr. Daniel O'Brien of the Johns Hopkins Hospital, left Baltimore, March 31, to join the arctic aerial expedition in command of Lieut. Comdr. Richard E. Byrd, Jr., U. S. Navy, retired, which sails from New York, April 2, for Spitzenbergen. Dr. O'Brien was head of the Grenfell expedition to the coast of Labrador in the summer of 1920; he graduated from Yale and the Johns Hopkins Medical School and served in the army during the World War, and spent two years in Egypt and the Near East; except for the Labrador expedition, he has been on the staff of the biologic department of the Johns Hopkins Medical School since returning from the Mediterranean countries.

MICHIGAN

Personal.—Dr. George F. Inch has been appointed general medical superintendent of the state hospital at Traverse City, and Dr. Roy A. Morter has been appointed assistant medical superintendent of the state hospital at Kalamazoo, to succeed Dr. Inch. Dr. Morter has been on the staff of the Kalamazoo Hospital a number of years.——Dr. Pitt H. S. Wilson, Muskegon, has been elected president of the Muskegon County Tuberculosis Association.

Instruction in Health.—Dr. William R. P. Emerson, Boston, will conduct a nutrition and public health institute at Grand Rapids, April 5-18, under the auspices of the Grand Rapids Child Health Bureau. There will be conferences and classes daily for (1) public health nurses; (2) members of the parent-teacher association, and (3) other interested groups. There will be demonstrations especially for teachers in the afternoon and a lecture every evening. Dr. Clyde C. Slemons, health officer, is general chairman of the committee in charge; one hour of college credit will be given those who complete the course and supplement the work with collateral reading. The subjects will cover social and mental hygiene, child behavior, child guidance, public health nursing, and home economics.

MISSOURI

Society News.—The Trudeau Club, St. Louis, will furnish the program, April 27, for the St. Louis Medical Society, and will present the modern conception of tuberculosis diagnosis and treatment; among the speakers will be Dr. Adelheid C. Bedal, whose subject will be "The Diagnosis of Concealed Tuberculosis;" Dr. Evarts A. Graham, "Thoracoplasty in the Treatment of Pulmonary Tuberculosis," and Dr. Joseph W. Larimore, "The Diagnosis and Treatment of Gastro-Intestinal Tuberculosis."

Donors for Blood Transfusion.—A committee of the Community Council of St. Louis is making a permanent list of donors for blood transfusion; sixty-seven persons have responded to the call. It is hoped that the list will be increased to 100, and that negroes as well as Caucasians will volunteer. The donors are being examined to rule out disease and to have their blood typed. The names of those accepted will be certified to the Central Nurses Registry; they will be placed at the service of all hospitals and reputable physicians in the city; eight hospitals are represented on the committee at present. It is planned to give donors a fee of $25; many have offered their services free of charge.

NEW JERSEY

Warning.—Prescription Books.—A correspondent writes that a well dressed man has visited the offices of several physicians in Newark, recently, when the doctors were out, and asked permission of the attendants to leave a note on the doctor's desk. When these physicians returned, they found that their liquor prescription books were missing.

Society News.—Dr. Richard A. Kern, associate professor of medicine, University of Pennsylvania School of Medicine, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, February 12, on "The Diagnosis and Treatment of Hay-Fever."——The Bergen County Medical Society, Hackensack, passed a resolution at its February meeting thanking the board of freeholders for its efficiency in keeping the county roads clear in spite of heavy snowfalls.

NEW YORK

Veterans' Hospital at Northport.—The director of the U. S. Veterans' Bureau has planned to construct a 1,000-bed fireproof hospital at Northport, L. I., on about 550 acres of land, which will comprise about twenty-five buildings and cost about $3,000,000. Construction will start early this spring.

Appointments and Promotions at State Hospitals.—The following appointments and promotions at state hospitals were reported in the February number of the *State Hospital Quarterly:*

Dr. Katherine C. Brockman, appointed assistant physician in Kings Park State Hospital.

Dr. Bernard J. Dolan, appointed assistant physician in Buffalo State Hospital.

Dr. J. B. Ferran, Jr., assistant physician in Binghamton State Hospital, promoted to senior assistant physician.

Dr. Ross D. Helmer, appointed medical director at Marshall Sanitarium, Troy, N. Y.

Dr. William E. Kelly, senior assistant physician in Middletown State Homeopathic Hospital, promoted to pathologist.

Dr. Louis F. LeSoine, assistant physician in Hudson River State Hospital, promoted to senior assistant physician.

Dr. Paul Levi, appointed assistant physician in Gowanda State Homeopathic Hospital.

Dr. Paul C. Lybyer, assistant physician in Hudson River State Hospital, promoted to senior assistant physician.

Dr. Christopher J. Patterson, appointed assistant physician in Hudson River State Hospital.

Dr. Albert Slutsky, appointed assistant physician in Kings Park State Hospital.

Dr. Ernest S. Steblen, assistant physician in Binghamton State Hospital, promoted to senior assistant physician.

Dr. Harry A. Steckel, senior assistant physician in Binghamton State Hospital, promoted to clinical director.

Dr. Nellie N. Tilton, assistant physician in Hudson River State Hospital, appointed assistant physician in Middletown State Homeopathic Hospital.

Dr. August E. Witzel, senior assistant physician in Utica State Hospital, transferred to the position of director of clinical psychiatry in Brooklyn State Hospital.

Dr. Claude R. Young, assistant physician in Binghamton State Hospital, promoted to senior assistant physician.

New York City

Seventh Harvey Lecture.—Dr. B. Brouwer, professor of neurology, University of Amsterdam, will deliver the seventh Harvey Lecture, April 17, in the evening, at the New York Academy of Medicine, on "Comparative Anatomy and Nerve Pathology."

Measles Serum Wanted.—The department of health will send an official to secure a specimen of blood for convalescent measles serum to any patient from whom the attending physician has obtained consent, and will reserve for the physician who obtained consent, a supply for his future use; from $10 to $25 will be paid to a poor patient who wishes to be paid for the specimen. The health department has been using convalescent serum as a prophylactic measure in infants exposed to measles during the last four years. The supply has been limited; recently, to obtain serum that it might be offered to a larger number of practicing physicians, the department sent a representative to Kentucky, there having been an epidemic of measles in the University of Berea, where for a small sum, sixty students were willing to contribute specimens; the expense entailed was paid by a New York life insurance company.

Hospital News.—The health commissioner, Dr. Louis I. Harris, in an address before the New York Visiting Committee of the State Charities Aid Association, March 4, deplored the condition of the city hospitals; he said, according to *New York Medical Week*, that "our hospitals today stand as a monument to things outgrown." The condition was attributed to old cement buildings which do not permit the installation of elevators and scientific administration. There are in some of the hospitals, it appears, "dirty kitchens" with adjacent "garbage heaps"; patients still have to cross the East River in old, open boats, subject to delay and exposed to the cold. Riverside Hospital was especially mentioned.——The Flushing Hospital Corporation, Flushing, has voted to begin a campaign, May 1, to raise $750,000 to enlarge the institution, for which a plot of ground has been secured at Elm Street and Parsons Boulevard.——Montefiore Hospital will build a new sanatorium for tuberculosis patients in the spring on the site of its present institution at Bedford Hills in Westchester County; the sanatorium will cost $1,500,000 and will accommodate 230 patients.

OHIO

Influenza at Cleveland.—Three hundred and fifty teachers were absent from the public schools of Cleveland, March 22, it is reported, largely because of an epidemic of influenza, which, it was said, also was largely responsible for the absence of about 12,000 pupils.

Miscellaneous Items.—The Toledo Safety Council has completed arrangements to equip all taxicabs with first aid kits.——Dr. Guy H. Swan has announced his retirement from active practice.——The children's building of the Clark County Tuberculosis Sanatorium will not open this year as planned, on account of a lack of funds.——A drive to raise a half million dollars in Akron to construct a children's hospital is expected to open this month.——Official charity in Ohio last year cost $9,572,470.35, the greater part of which was spent for the maintenance of the twenty-four state institutions.——Dr. William A. Koch of Bucyrus was fined $500 and costs in federal court, March 8, it is reported, after pleading guilty to a charge of issuing liquor prescriptions without having made a physical examination.——A group of citizens of Marion have presented an automobile to the city health department for the use of the "city health nurse."

PENNSYLVANIA

The Bedford Lecture.—Dr. Beverly R. Tucker, Richmond, Va., will deliver the Bedford Lecture, April 8, at the Duquesne Club, Pittsburgh, 7 p. m., on "The Doctor's Contribution to Literature." Members of the Allegheny County Medical Society are invited. Reservations for the dinner preceding the lecture can be made by calling Mrs. Risacher, Grant 0400.

Westmoreland County Annual Clinic.—The fifth annual clinic and banquet of the Westmoreland County Medical Society will be in Greensburg, May 6. The clinic will be at the

New Armory in the afternoon, and the banquet at the Country Club in the evening. Adjacent county medical societies are cordially invited to both functions. Dr. Elliott P. Joslin, clinical professor of medicine, Harvard University Medical School, Boston, and Dr. Frank H. Lahey, Boston, will conduct the clinic.

Personal.—Dr. and Mrs. William C. Mitchell celebrated their fiftieth wedding anniversary at a reception at the Hotel Rittenhouse, recently.——Dr. Edwin Bosworth McCready, Pittsburgh, addressed the Academy of Medicine of Richmond, Va., March 11, on "Nervous, Backward and Delicate Children."——Dr. Herbert H. Holderman, Philadelphia, has been elected chief surgeon at the new Locust Mountain Hospital, which has been in the process of construction for about ten years, it is reported. The state department of health will announce the opening date of the hospital within a short time.——Dr. Park A. Deckard has been appointed chief of the department of dermatology at the Harrisburg Hospital; Dr. Allen B. Dalton, Chester, has been appointed chief resident at the hospital.——Dr. George A. Reed has been elected president of the Erie Anti-Tuberculosis Society, to succeed the late Edward P. Selden.——Dr. William L. Steen has been reappointed health officer of New Castle.

Philadelphia

Personal. — Dr. Benjamin Lipshutz has been appointed attending surgeon of the Mount Sinai Hospital, Philadelphia.——A testimonial dinner, March 23, was given in honor of Dr. Francis Edward Stewart by the faculty of the Philadelphia College of Pharmacy and Science and friends.——The Medical Club of Philadelphia will give a reception in honor of Dr. Francis B. Haas, superintendent of public instruction of Pennsylvania, at the Bellevue-Stratford Hotel, April 16.

Society News.—Among others, Dr. Pascal Brooke Bland addressed the Northern Medical Association of Philadelphia, March 15, on "The Newer Advances in Obstetrics," and Dr. John F. Sinclair on "The Care of the Premature New-Born."——Dr. Francis Carter Wood, Columbia University College of Physicians and Surgeons, New York, addressed the Philadelphia County Medical Society, March 24, on "The Cause of Cancer with Special Reference to the Gye-Bernard Work"; Dr. John A. Kolmer, Dr. Jay F. Schamberg and Malcolm J. Harkins, on "Concerning Gye's Hypothesis of the Etiology of the Malignant Tumors," and Dr. George E. Pfahler, on "Present Value of Physical Agents in Treatment of Malignant Diseases."——Dr. Albert C. Buckley presented a case of chorea in the seventh decade with apparent recovery before the Philadelphia Neurological Society, March 26, and among others, Dr. Abraham M. Ornsteen discussed "Differences in Muscle Contraction in Peripheral and Central Facial Paralysis."

RHODE ISLAND

Dr. Scamman Resigns.—Dr. Clarence L. Scamman, deputy superintendent of health of Providence, resigned, April 1, and has accepted an appointment as deputy commissioner of health and director of the division of communicable diseases of Massachusetts; he has been with the Providence Health Department about four years. Dr. Scamman will also lecture at the Harvard University School of Hygiene, it is reported.

TEXAS

Dr. Hartman Appointed Acting Dean.—The Board of Regents of the University of Texas has appointed Dr. Henry C. Hartman, professor of pathology at the university, as acting dean of the medical school, to succeed Dr. William Keiller, who has remained on duty since tendering his resignation to the board last May. Dr. Keiller has been associated with the university as professor of anatomy, since 1891. Dr. Hartman has been associated with the pathology department of the university since 1908, and has been professor of pathology since 1913; he was formerly assistant state health officer and state bacteriologist; he served in the navy during the World War (The Journal, June 6, 1925, p. 1757).

WASHINGTON

Virulent Smallpox.—It was reported March 22, that eighty-four cases of virulent smallpox and twenty deaths had been reported in Seattle since January 21; about 25,000 persons in the city had been vaccinated in the last month.

WEST VIRGINIA

Society News.—The West Virginia Newspaper Publishers' Association voted unanimously at the annual meeting in Wheeling, February 12, to support the West Virginia State Medical Association in its campaign to educate the public in matters of health; Mr. Sterrett O. Neale, executive secretary of the medical association, among others, addressed the meeting.——Drs. Merrick F. McCarthy and William L. Shannon, Cincinnati, addressed the Kanawha County Medical Society, recently, on "Vertigo" and "Diagnostic and Prognostic Significance of Precordial Pain," respectively; the program for the February 2 meeting was a symposium on empyema by Drs. Robert Douglas Roller, Jr., Arthur A. Shawkey and John E. Cannady of Charleston.——The Barbour-Randolph-Tucker Medical Society authorized the secretary to provide the four members of the legislature and three members of the state senate with subscriptions to *Hygeia*, a journal of individual and community health, published by the American Medical Association.——Dr. John P. Griffith and James D. Heard, both of Pittsburgh, addressed the Ohio County Medical Society on "Ulcer of the Stomach and Duodenum" and "Prevention and Relief of Heart Disease," respectively.

GENERAL

Annual Dinner of Camp Merritt Officers.—The annual dinner of the Camp Merritt Base Hospital Officers' Association will be held, Saturday evening, April 10, at the Princeton Club, Park Avenue and Thirty-Ninth Street, New York City. Brig. Gen. James L. Kennedy, who, during the World War, was surgeon of the Port of Embarkation, Hoboken, N. J., and who now is assistant surgeon general of the army, will be the guest of honor.

Society of Medical Hydrology.—The International Society of Medical Hydrology will visit Czechoslovakia, and persons who would like to join the party should apply at once to the Honorary Secretary, 36 Devonshire Place, London, W. I., England; April 16 will be spent at Karlsbad; the party will then go to Marienbad, Franzenbad, Prague, where there will be a reception, Pistany, and, April 21, to Tatra Spas; at each place there will be scientific meetings.

Women Physicians.—Dr. Leora G. Bowers, Dayton, Ohio, president-elect of the Ohio State Medical Association, recently addressed the eighth councilor district at Lancaster on "Education for the Physician of the District."——Dr. Josephine Milligan, Jacksonville, Ill., has been elected president of the Morgan County Medical Society.——Dr. Florence M. Olmsted has been elected president of the board of health of Kokomo, Ind.——Dr. Esther Loring Richards, associate professor of psychiatry, Johns Hopkins University Medical School, Baltimore, recently addressed the annual meeting of Infant Welfare Society of Chicago on "Child Behavior."

Sanitary Regulations for Garages.—Tentative regulations for the manufacture and use of tetra-ethyl lead gasoline and for the sanitation of garages have been made by the Surgeon General of the U. S. Public Health Service and submitted to health officers of the various states for comment and suggestions. In formulating these regulations, the Surgeon General intends to establish approved standards of health in the manufacture and handling of dangerous chemicals. During the recent investigations of the public health service of the health hazard in the use of tetra-ethyl gasoline, it was found that lead was present in the dust of ordinary garages. There are thousands of garage workers throughout the country; the extent of this health hazard is apparent and the necessity for sanitary regulation is obvious.

Tables at Woods Hole.—The biologic laboratories of the U. S. Bureau of Fisheries at Woods Hole, Mass., Beaufort, N. C., and Fairport, Iowa, will open June 21, and remain in active operation until September 15. Owing to the increased demand for accommodations at Woods Hole, it is necessary to use more care in the selection of those who work at the laboratory; preference will be given to investigators who work along the lines of especial interest to the bureau of fisheries and who have shown ability for energetic and productive research. There is a new and well equipped laboratory at Fairport, Iowa, with collecting apparatus, ponds and tanks. Workers desiring to have the use of tables and other facilities at these laboratories may communicate with Henry O'Malley, Commissioner of Fisheries, Washington, D. C.

American Association for Medical Progress.—During 1925, the American Association for Medical Progress received requests for lectures from all parts of the country; it was possible to send a representative to speak in twenty-five cities in eleven states, and to confer with the deans of medical schools, health officers, heads of educational and research institutions and city superintendents of schools. The association distributed about 98,000 pamphlets to the public and its members, and the lay press published announcements and news items regarding medical discoveries and editorials about the work. There was interest in different parts of the country in the formation of local branches of the association, and one active branch was established at Santa Barbara, Calif. An obstacle to the formation of local branches is the problem of adequate division of financial responsibility, particularly where groups interested in health and related problems are affiliated through "community chests" or similar agencies; another obstacle arises from the desire of the association to be uninfluenced by the medical profession, since voluntary health organizations are in close cooperation with physicians in practically all cities. The association took no active part in 1925 in promoting or opposing legislation. The board of directors voted to raise the dues for associate members to $2 and to establish a class of special members, with an annual payment of $1 for teachers, trained nurses and associate workers. The Beth Israel Hospital, New York, voted to subscribe $1,000 a year for the work of the association and to designate five of their number as members. The activities of the year consisted largely, therefore, in making contact with interested groups in various parts of the country, in distributing printed material, in getting information into the newspapers, and in surveying the needs for further work.

News of Epidemics.—The recent epidemiologic reports note especially outbreaks of influenza; some state that the incidence of influenza is equal to or greater than in the pandemic of 1918; business houses and the public schools in some communities report many absentees, and some schools have closed. The severity of the epidemic, generally, has been reported as mild, although the number of deaths from pneumonia, which normally is high at this season, has been increased; for example, eighty-seven persons were reported to have died from influenza in New York City the week previous to March 21, and 608 persons died from pneumonia; this was said to be the greatest weekly number of deaths since the outbreak began. The rates of incidence and mortality of influenza in the army are noted in this issue under Government Services.——Several cases of cerebrospinal meningitis and one death were reported from Boise, Ida., March 20.——A new outbreak of three cases of smallpox occurred at Rockford, Ill., March 12; several cases of smallpox were reported from Mansfield, Ohio, March 18.——One hundred and seventy-six new cases of measles were reported during the week ending March 14, at Saginaw, Mich., bringing the total number under quarantine in the city to about 300; there had been 456 cases of measles reported in Louisville, Ky., between February 1 and March 15.——Grand Rapids, Mich., reported 308 cases of whooping cough for the month of February, as compared with eleven cases for February last year.——The secretary of the Indiana State Board of Health issued a warning, early in March, concerning the prevalence of rabies in Indiana, stating that seventy-nine persons who had been bitten by rabid dogs since Oct. 1, 1925, had been treated by the state laboratory, and that in the week preceding his report, five cases of rabies from different parts of the state had been identified through the examination of the brain of animals received at the laboratory.

CANADA

Tuberculosis Research.—Dr. Auguste Pettit of the Pasteur Institute, Paris, has accepted an invitation to take charge of the tuberculosis research work to be carried on at the University of Montreal, in connection with the dominion-wide program, planned by the Research Council of Canada. The details of the program at the University of Montreal will not be arranged until Dr. Pettit arrives; the university will have the medical and scientific direction of the hospital being erected at Cartierville, in which 200 beds will be allotted for tuberculosis patients. The other center of tuberculosis research in the Canadian program will be at the University of Toronto.

Extramural Postgraduate Work.—The Canadian Medical Association has appointed two committees for the purpose of organizing extramural postgraduate instruction, one for the province of Quebec, the chairman of which is Dr. Rodolphe Boulet, and the other a central postgraduate committee for the remainder of Canada. The latter committee is engaged in making a schedule of lectures in cooperation with the provincial associations and universities. There is interest, generally, in this work, the general secretary of the association observed in recent visits throughout Canada. The profession is being organized into sectional groups, which are ready to welcome the visiting speakers, and funds to the extent of $30,000 for one year have been received through a gift of the Sun Life Insurance Company.

LATIN AMERICA

Personal.—The *Repertorio de Medicina* of Bogota states that Dr. Miguel Jiménez López has been appointed minister from Colombia to Berlin, and Dr. Vergara Rey secretary to the Colombian legation, while Dr. Jorge Bejarano has been appointed secretary to the Colombian legation at Paris.——The national public health authorities, faculty of medicine and medical societies of Bogota joined in a tribute to Dr. Juan David Herrera, Bogota, on the completion of his fiftieth year of practice, presenting him with an illuminated parchment testimonial.——The past and present pupils of Dr. García Valenzuela, professor of physiologic chemistry at the university of Santiago de Chile, gathered on the occasion of his retirement from the chair he has held for thirty years to pay him honor and recall his contributions to chemistry and histology.——The *Clínica* states that Dr. E. Prado Tagle, president of the Santiago Medical Society, and many of the members are working industriously to organize the profession in Chile into a medical syndicate to study ways and means to promote the material welfare of the profession.——Dr. B. Galíndez, president of the Círculo Médico of Cordoba, has inaugurated a campaign against quacks, urging physicians throughout the province to obtain authentic proof of quack practices and injury therefrom so that collective data can be presented to the courts. The organized lawyers are working to have the laws modified to expedite legal relief from the plague of quackery.

FOREIGN

Competition in First Aid Supplies.—The international committee of the Red Cross is to hold at Geneva a competitive exhibition of litters, litter holders, cards for the wounded, and individual first aid packets. Specimens of the competing articles should be sent with full description to the organizing committee, promenade du Pin, 1, Geneva, Switzerland, before June 30, 1926.

League for Sexual Ethics.—The *Wiener klinische Wochenschrift* states that the society organized by Prof. E. Abderhalden, Halle, entitled the Medical League for Sexual Ethics, has been reorganized as a general society to include laymen, and to enlarge the scope of the work to include professional and social ethics. The name of the journal published by the society is *Ethik, Sexualethik und Gesellschaftsethik*. The official name of the society is now the Aerzte- und Volksbund fur Sexual- und Gesellschaftsethik, with headquarters at Magdeburgerstrasse 21, Halle.

Personal.—Drs. Moureu and Fourneau have been appointed to represent the French Académie de médecine at Paris in the Italian congress on pure and applied chemistry, to be held at Palermo in May.——A gold medal was recently presented to Dr. Angel Pulido, honorary director of the *Siglo Médico*, Madrid, perpetual secretary of the Academia Nacional de Medicina, by the Colegio de Doctores of the University of Madrid, in tribute to his services to medical science.——The Urologic Society of Vienna has elected Dr. A. Pulido Martin, Madrid, as honorary member.——Dr. Henry Plotz of the Pasteur Institute, Paris, France, has been made a foreign member of the Société de pathologie comparée.

New Clinical Research Laboratory in Australia.—A new building for the department of biochemistry at the Alfred Hospital, Queensland, Australia, said to equal any of its kind in Great Britain, was formally opened, January 22, by Dr. M. T. MacEachern of Chicago, who is in Australia surveying the hospitals. The new laboratory has nine rooms and is in charge of Dr. A. Basil Corkill. The upkeep of the department has been assured for five years by Mr. T. Baker, who intimated that if the department "makes good" his support would not be withdrawn at end of that period. Although now designated as a biochemical laboratory, the intention is to broaden its scope, so that it will be a clinical research institution.

Deaths in Other Countries

Dr. H. Kantor, who for thirty years from his home in Warnsdorf, Bohemia, waged a valiant fight against quackery, founding and publishing the *Gesundheitslehrer*, a special organ to combat medical fakers, aged 67. One of our German exchanges says, "All that has been accomplished here in recent decades in the fight against quackery is due mainly to Kantor."——Dr. **I. Bandi**, professor of hygiene and colonial pathology, Naples, and founder of the Istituto sieroyaccinoterapico, aged 59. Dr. **Arthur Robertson Cushny**, professor of materia medica and pharmacology, University of Edinburgh, died suddenly at his home in Edinburgh, February 25, of cerebral hemorrhage, aged 60. Dr. Cushny was formerly professor of pharmacology at the University of Michigan, Ann Arbor, from 1893 until 1905, and professor of pharmacology at University College, London, from 1905 to 1918. He was the president of the Section of Pharmacology and Therapeutics of the British Medical Association in 1910, and for years a member of the Scientific Grants Committee of that association. He was the author of a well known textbook on "Pharmacology and Therapeutics or the Action of Drugs"; his name is particularly associated with his work on the action of digitalis.——Dr. **Michael Francis Cox**, president of the Royal College of Physicians of Ireland in 1922, and a member of the privy council; senior physician to St. Vincent's Hospital, Dublin.——Dr. **John B. Story**, president of the Royal College of Surgeons in Ireland from 1918 to 1920, and president of the Ophthalmological Society of the United Kingdom, professor of ophthalmic surgery to the Royal College of Surgeons in Ireland, president of the Irish Medical Association in 1913, and surgeon oculist to the king in Ireland.

Government Services

Influenza in the Army

Influenza appeared in the army in mild epidemic form in January and increased in extent in February, the rates of incidence being 97.26 and 158.21, respectively. Influenza was more prevalent in February of this year, the Surgeon General's Office says, than during February of 1921, 1924 and 1925, but less prevalent than in February of 1920, 1922 or 1923. Up to February 20, no stations on the New England Coast or the Pacific Coast had reported an unusual number of cases of influenza, but stations in other parts of the country reported outbreaks. Fort Slocum, N. Y., had up to February 27 the most serious outbreak, with 286 cases and twenty-two cases of pneumonia. The most reliable indication of the severity of these outbreaks of influenza, the Surgeon's General's Office says, is the relative number of cases of pneumonia. The combined rate from the pneumonias in January was 5.20 and in February 7.69, which was considerably higher for January than during the corresponding month in 1925 (3.32), or in 1924 (3.52), but lower than in 1923 (5.33); it was lower, however, during February, 1926 (7.69) than in February, 1925 (8.84). It is apparent, it is said, that the army has had a rather extensive epidemic of influenza, but that it has been relatively mild.

Veterans' Bureau Medical Corps

An amendment to the World War Veterans' Act for the creation of the U. S. Veterans' Bureau Medical Service, which shall consist of a medical corps, a medical reserve corps and a nurse corps, has been approved by the house committee on World War veterans' legislation and is now on the calendar of the present Congress. Legislation of this character has for more than two years been under consideration by the Veterans' Bureau and has been the occasion for conferences by the director of the bureau, with members of Congress and President Coolidge. The object is to stabilize the medical personnel of the Veterans' Bureau. An important provision of the amendment is that "every person under the provisions of this act shall receive an increase of 5 per cent of the base pay for the period in which he is serving for each three years of service up to thirty years." In computing such service for members of the medical corps, there shall be counted the service of physicians in the U. S. Veterans' Bureau since Aug. 9, 1921, and all service on active duty in the medical service of the U. S. Veterans' Bureau. Provision is also made that each member of the medical corps, on active duty, shall be entitled to a money allowance for subsistence and for the rental of quarters, where public quarters are not available. The amendment is drawn along lines identical with those for the medical personnel of the army and navy. The present indications are that the war veterans' bill, which includes this amendment, will be passed at this session of Congress.

Foreign Letters

LONDON

(From Our Regular Correspondent)

March 6, 1926.

Lord Dawson on Osteopaths

Lord Dawson of Penn, physician to the London Hospital, addressed a meeting of members of both houses of parliament at the House of Commons on "The Medical Profession, the General Medical Council, and the Public." The meeting was organized by "the Parliamentary Medical Committee" (physicians who are members of parliament). He said that the merits of the subject had become obscured by personal grievances and heated comment. At present there was considerable criticism of the medical profession, and there were not a few suggestions that the physicians were actuated by selfish motives. Their critics misunderstood them. He asked them to contemplate the physician's life—his long hours, his sacrifice of ease and leisure, his contact with other people's troubles. Was it likely that such men would pursue a selfish policy? True, they had their foibles. They did not like a man who thought he had made a discovery making a secret of it; and if they found that associated with that secrecy there was gain, they claimed the right to cast him from them. This illustrated that in their ideals they put achievement before money. They liked their men, especially if they were successful, to give up some of their time to unremunerative work for the public good—it might be work in the wards of hospitals, in free clinics of their own, or in research laboratories. Further, they were philanthropic enough to inculcate principles of health which, if they were carried out, to a large extent would deprive them of their practices. It was a fortunate circumstance that the public did not always incline to follow their advice, and, therefore, the physicians were still in being. He laid down two guiding principles: (1) The good of the public should ever be the overriding consideration; and (2) the medical profession should use knowledge in whatever quarter it could be found, provided it was for the benefit of the people. They in no way contemplated that unqualified practice should be forbidden by legal enactment. They were concerned with whether it should receive recognition by the state and the medical profession. The necessary preliminary to the treatment of disease was knowledge of disease. To get this knowledge, the members of the medical profession went through five and one-half years' training. This training was necessary, whatever the physician's line of practice might ultimately be. It would be criminal in the interests of this nation to make the smallest compromise on this question—that there can be no treatment of disease by any one who has not made a thorough study of its nature and its diagnosis. If the osteopaths wished to further their cause, let them select able students and put them into the medical faculty of the university, and when trained let them espouse the cause of osteopathy. There was a place for the gifted bonesetter and the osteopath and for other skilled persons. They were welcome; but, to do good, all methods of treatment must be coordinated under general medical guidance. It was the medical profession's duty to protect the public from exploitation by "stunts" and fancies. On the personal side, Sir Herbert Barker by good fortune succeeded to the practice of the famous bonesetter Hutton. The success of manipulative surgery depended on the use of gifted fingers; in suitable cases such treatment was valuable, but when it was employed in unsuitable cases harm resulted. He admitted that the best of the manipulative surgeons were excellent, but the average men about the country were far from that; and when he thought of the "booming" of those manipulative surgeons by parliament and the press he thought it was laughable to hear their names proclaimed as great pioneers when Great Britain was the proud possessor of the man of genius in manipulative surgery whose reputation was world wide—Sir Robert Jones—whom they never mentioned. Sir Robert Jones had more wisdom in his little finger than the whole lot of them.

Death from Diphtheria Under Christian Science Treatment

The death of a school girl was inquired into by the coroner for West Kent. The child went to a boarding school associated with Christian science. While there last Thursday she developed a sore throat. The head of the school called in a physician, who said he thought it was a little septic, and that she had better be sent home. The mother was a Christian scientist. The child was taken home, and a Christian science treatment adopted. Monday morning the child seemed dangerously ill, and a physician was summoned who formed the opinion that the child was almost dying from diphtheria. He called in the health officer, who confirmed the opinion. Later the child died from diphtheria. A health officer went to the school and found another girl with diphtheria, who was removed to a hospital. He took all steps at once to have the place disinfected and the pupils examined. The mother said she telephoned to a Christian scientist when the child was brought home, and the work was begun the moment she ceased speaking. The coroner: "What is the nature of the treatment?"—"That is a deep question. When we are healers ourselves we can answer that." After a pause the witness added, "Prayer." She said that the name of the first practitioner was Commander Burt. She telephoned to him for immediate prayer. The next day the little girl had improved. Afterward a Mr. Cousins was called in and saw the child, and he told her to telephone if she wanted more help in the night. In the morning she telephoned him again and told him that the child had not had much sleep during the night and she thought it would be nice if she could have sleep during the day. He continued helping her. The coroner: "By prayer, you mean?"—"Yes. Always by prayer." "And prayer alone?" —"Yes. Oh absolutely, prayer and prayer alone. She was much better on the Sunday." The coroner: "If you had known that the child was suffering from diphtheria would you have still persisted in relying on the Christian science treatment?" The mother said she would have had a physician but would have continued with prayer, which no one could gainsay, as in a former case when the child had whooping cough. A juryman asked her whether she knew that had she called a physician the child would probably have been alive today. She replied: "It is a matter of opinion. I have known cases where friends have had specialists who had given them up and Christian scientists' prayers have restored them to life. So you see, one can never tell one way or another." Dr. P. D. Cogswell gave it as his opinion that death was due to syncope from diphtheria. The coroner said it was a very sad case. The mother held strange views from their point of view, but yet deep religious views. It seemed to her that the power of prayer could do more than science by the physician. She honestly believed that now, but she did go further, and say that if she had known the child was suffering from diphtheria she would have called in a physician at once, and also gone on with Christian science treatment. Was she guilty of such neglect as to make her criminally liable? He did not think there was any suggestion of that. There was no doubt she was very fond of the child, but was very misguided. The jury returned a verdict in accordance with the medical evidence. This means that no legal charge of neglect was made against the mother. This has always been the result in these sad cases, the jury evidently holding that, however misguided the parents, they cannot be blamed if they acted in good faith.

Antiquity of the Ape

In a lecture at the Royal College of Surgeons, Sir Arthur Keith reviewed the present state of knowledge relating to the antiquity of man's nearest relatives, the anthropoids. Describing finds in stratified deposits left to the west of Cairo in the estuary of a great vanished river, an ancient predecessor of the Nile, he said that in 1910 was found, in the deposits of older oligocene date, a fossil fragment of the lower jaw of an ape. That jaw gave most definite evidence that a small form of anthropoid ape—now represented by the gibbons, which inhabited the Malayan forests—had come into existence at this remote period. The modern gibbon was a pigmy compared to the gorilla or chimpanzee, but this ancient ancestor of the gibbon was a pigmy compared to its living descendants. The gibbon had sprung from an ancestor little bigger than the marmoset. A discovery made in 1924 by Dr. Fourtan of the Egyptian geological survey showed that in the miocene period the African gibbon had almost the size of its modern representatives. That the gibbon should have appeared so early in geological records did not surprise those who had studied its anatomy. In its structure it showed relationships to monkeys of the New World, to the ordinary monkeys of the Old World, and to the great anthropoids. The gibbon was the central figure in the evolutionary movement which led on to the highest primates. More important from the point of view of those who were in search of a possible human ancestor was the appearance in the miocene deposits of Europe of large anthropoids, which we had every reason to suppose were evolved from a gibbon-like ancestor. There were at least three species of large anthropoids in Europe in later miocene times. Not any of them reached the size of the chimpanzee. Some of the teeth assigned to this extinct type of European ape had a certain resemblance to those of primitive humanity. In the miocene deposits in the southern foothills of the Himalayas, officers of the Indian geological survey had discovered the remains of at least five great anthropoids. Some of these exceeded the chimpanzee in size. Some of them might represent ancestors of the gorilla, chimpanzee and orang. As the geological evidence stood, we might conclude that great anthropoids came into existence somewhere between the end of the oligocene period and the middle of the miocene period. It was not until a great anthropoid stage was reached that human evolution became possible.

Physician's Bequest of His Body

Sir Robert Charles Brown of Preston, Lancashire, consulting medical officer to the Preston Royal Infirmary and other institutions, who died, November 23, 1925, aged 89, left $403,580. To the Cambridge University Research Hospital, Sir Robert left $5,000 and his body, authorizing them to retain such parts of his body as they may consider to be suitable additions to their pathologic museum, and requesting them to place in the museum a glass bottle containing the ashes left by the cremation of his remains, together with a statement of the weight of the ashes and his "average normal weight, which has been 11 stones [70 Kg.]."

Food Poisoning from a Duck Egg

At an inquest on a woman, aged 24, Mr. John Webster, government analyst, stated that he found *Bacillus aertrycke* in enormous quantities in the organs. The woman and four other members of the family had a meal of duck's eggs, after which she was taken ill and died. Dr. D. L. Thomas, health officer for Stepney, stated that *Bacillus aertrycke* was relatively heat-resisting, and boiling for a time did not destroy it. As far as he could make out, there had been no record in the United Kingdom of any cases of food poisoning from eggs. There was no doubt that bacteria could penetrate the shell into the egg.

BUENOS AIRES

Feb. 8, 1926.

Control of Biologic Products

Heretofore, only imported serums and vaccines have been standardized. For the last two years, the national health department has been examining both imported and domestic organotherapic products, as well as foreign-made insulin. No control, however, has been exercised over domestic insulin and serums. This deficiency is about to be remedied. The director of the bacteriologic institute has suggested, and the president of the national health department has approved, the creation of a control office charged with the duty of supervising all serums, vaccines and biologic products, and testing their potency and sterility. This measure will be compulsory for both foreign and home products, including those manufactured by the bacteriologic institute itself.

Hospital Enlargement

The reconstruction of the Rawson Hospital is making much progress. There are now 1,200 men working in day and night shifts in order to complete the task within three months. Work will immediately be started on the Ramos Mejía Hospital. When this is completed, there will be 2,600 more beds available in the city hospitals. The cost of each bed is placed at not more than 2,500 pesos ($977). This is quite cheap, according to prices here. The committee in charge of the work authorized an expenditure of 1,100,000 pesos (about $430,000) in addition to the 18,000,000 pesos ($7,000,000), already voted for hospital improvements.

Dental Congress

The Second Latin American Odontological Congress, held recently here, has just issued its resolutions and conclusions. The next congress will be held at Rio de Janeiro, under the auspices of the Latin American Odontological Federation. The emblem suggested by Dr. Carrea was adopted. It was agreed that dentists must graduate as M.D.'s; that the standing of dentists serving in the army and navy must be raised; that dental courses must be unified in the different countries, and that the right of privileged communication must remain undisturbed.

New Journal

The Public Assistance Society, which receives part of its funds from the government, supports several large hospitals. In these, 354,323 patients were treated during the year 1924, and 15,028 operations were performed. The Children's Hospital and the Eye Hospital are already issuing journals of their own. The officers of the society have decided to publish another journal, entitled *Archivos de los Hospitales,* in which the scientific work done at its institutions will be recorded. The editor is Dr. A. Ovenard, and the editorial board includes Drs. P. de Elizalde, F. Etcheverry Boneo, S. Madrid Páez, A. V. Marque, H. Mascheroni, J. Nogués, A. Rodríguez Egaña and F. J. Soriano, of the different hospitals interested.

Tuberculosis Institute

The Agricultural and Veterinary School has offered a large lot to house the proposed Institute for the Study and Treatment of Tuberculosis, a new enterprise approved by the superior university board at the suggestion of Prof. G. Aráoz Alfaro. Its promoter started the collection of funds with a gift of 100,000 pesos (about $39,000), but the money is coming in very slowly.

Insurance Societies Run by Physicians

While large insurance companies as well as friendly and accident insurance societies that have developed in the last few years had showed large surpluses, the physicians employed by them have received scanty salaries. This started a movement, headed by the Argentine Medical Syndicate, for higher medical fees. Then the physicians started in their turn general insurance societies, especially for workers and salaried persons. "La Primera," the first to organize in Buenos Aires, has already met with much success and general approval. Local physicians are now trying to launch a similar society here under the name of "Unión Médica."

Personal

Drs. J. Ferrán and A. Gimeno, Count of Gimeno, are expected in Argentina this years from Spain. Ferrán is known for his cholera vaccine and his views on the mutation of the tubercle bacillus. He has here quite a number both of followers and adversaries. The technical inadequacy of his publications almost prevents full verification of his studies.

Effects of Dry Cupping

Recently, Dr. Jules Droin, at the Medical Clinic of the University of Geneva, investigated the effect of dry cupping on the leukocyte count and on the arterial pressure. His results have not yet been published. Of Droin's twenty cases, 65 per cent developed a leukopenia apparently due to the action of cupping; in 10 per cent the leukocytes decreased before the application of the cups; in 10 per cent there was a leukocytosis throughout the application, followed usually by a slight decrease in number. In 15 per cent no conclusions could be drawn, as the oscillations in the number of leukocytes were either insufficient or else offered no apparent relation to the action of the cupping. These results throw a new light on the contradictory results obtained by other observers. Fleury's white hypoglobulia probably is merely the leukopenia of shock, and the hyperphagocytosis of the Italian observers probably corresponds to the leukocytosis present in Droin's cases. Both maximum and minimum blood pressures were taken in sixteen of the twenty cases. In thirteen cases the drop in the maximum pressure averaged 8.43 per cent; in the minimum, 3.7 per cent. Droin found that the diastolic pressures corresponded with those of the maximum pressure, and he believes that a study of the latter is sufficient for the study of hemoclastic shock. Of the sixteen cases, 50 per cent were positive, 25 per cent doubtful and 25 per cent negative. Taking the total of twenty cases, 50 per cent were positive, 20 per cent doubtful and 30 per cent negative. Droin concludes that in the majority of his cases shock comparable to hemoclastic shock followed the application of the cups.

Problems of Heredity

In the course of two public educational days last month, the subject discussed was heredity. A. Ferriere explained the various theories of heredity and demonstrated the reality of acquired characters. He defined the biogenetic law as "a parallelism of childhood and race" and stated that this parallelism was a reality. The speaker pointed out that children's play has its origin in ancestral rites, hence an attempt should be made in directing children's play to graft new activities on ancient instincts.

Alcoholism and heredity was discussed by Dr. Oettli, chief secretary of the Swiss Antialcoholic Society. He pointed out that there were three times more tuberculous and degenerate children in alcoholic families than in others. Although poor housing, insufficient food and other causes enter into the etiology of this condition it was probable that soon we would have proof that the nucleus of reproductive cells would show changes produced by alcohol.

Dr. Tecon, physician to the hospital La Source at Lausanne, discussed tuberculosis and heredity. The idea that tuberculosis is always hereditary is false. It is essential that the children of tuberculous parents should be separated from the source of contagion.

Psychic heredity was dealt with by Dr. O. L. Forel, physician to the Metairie, at Lyons. Dr. Forel defended the rights of defective children, because they do not possess the means for overcoming the difficulties of life. They must be made to understand the necessity of marrying healthy partners in order to prevent mental defects in the offspring.

Edward Claparede, professor of psychology in the University of Geneva, lectured on evidence. Evidence is the recital of a previous event; it usually is false, although the witness does not intend to deceive. Evidence given by children is most often inexact; the child puts forward purely imaginary facts which he believes to be real.

Hypertonia or Essential Hypertension

The monthly lecture of the Medical Society of Geneva was delivered, February 25, by Dr. Emile Thomas of Geneva, his subject being Hypertonia or Essential Hypertension. In certain subjects a more or less constant high pressure was observed although none of the ordinary cardiovascular or renal lesions could be found clinically. Temporary hypertensions, such as Pal has described in lead poisoning and certain other conditions and the hypertonia observed by Ambertin in angina pectoris, are not to be included in the conditions under consideration. Renal and cardiovascular lesions cannot be absolutely eliminated. When the practitioner, after thorough examination, is unable to discover any lesions, his duty is to look elsewhere for the cause of the disturbance. The pathogenesis of these conditions is probably multiple. Dr. Thomas' personal researches, soon to be published, show that, in the rabbit, increased cholesterinemia produces a durable hypertension.

NETHERLANDS

(From Our Regular Correspondent)

Feb. 9, 1926.

Physicians of Railway Companies

The association of railway physicians has just celebrated its fiftieth anniversay. In his presidential address, Dr. Posthuma recalled the history of the association, which was founded to study the organization of first aid to the injured. The association developed until in 1899 a council was formed, which subjects the personnel to examination. The examinations as to fitness have been applied with rigor in order to insure security in passenger traffic. This has been due to the activities of the council. The president disapproves of free choice of physicians in the railway medical service, for the problems are of a special nature and can be solved only by physicians trained for the work. Besides examining applicants for employment, railway physicians watch over the personnel already in the service, to which is due in great measure the security of traffic.

Vaccination Against Pertussis

The Rijks serologisch Instituut of Utrecht recently supplied a number of physicians with a pertussis bacillus vaccine together with a questionnaire. Dr. Pondman has collated the results reported. Sixty-one replies endorsed vaccinotherapy, as against seven that reported more or less doubtful results. The reactions were very slight. Vaccinotherapy must be employed early, and it is more efficacious if the vaccine is polyvalent.

Periodic Medical Examinations

Certain life insurance societies that have relations with foreign organizations are advising their clients to undergo periodic medical examinations. This applies particularly to those who are insured for at least 5,000 florins ($2,000). The societies offer free examination by one of their physicians every three years. It is only a prophylactic measure against insidious disease and is not obligatory. Both patient and life insurance society will be benefited. In order to safeguard the prerogatives of the insured, no information will be given by the physician to the life insurance company.

Outings for Children

The Amsterdam society that provides rural outings for weakly and anemic children has been very active. The society has been able to comply with about 55 per cent of the demands made on it and has afforded about 5,000 children the opportunity of such a vacation. A comparative study indicates that winter outings are just as beneficial as those given in summer.

Dental Aid for Persons of Restricted Means

At Amsterdam an association entitled Amsterdamsch medisch Instituut voor Tandheelkunde has been formed to aid persons of restricted means to secure dental care. In this manner it proposes to combat the practice of dentistry by inexperienced persons, so-called dental mechanics, and to awaken greater interest in mouth hygiene. It is thought that the work will eventually give rise to a group of medical stomatologists. Fears have been expressed by regular graduate dentists that their practices will be interfered with. However, the dental clinic will accept only patients who can pay a moderate but not a private dentist's fee. Then, again, the agitation in favor of mouth hygiene will show to the whole population the necessity of dental care. In this manner, what is lost in one way will be regained in another. The institute will not be administered for profit, but free treatment will not be given. The fees paid must cover the cost of the equipment and the operating and administrative expenses.

Regulations Pertaining to the Sale of Milk and Bread

A new law provides that the following persons be excluded from the manufacture, the handling and the transportation or distribution of bread: persons affected with abscess, suppurating wounds or cutaneous diseases of the head, arms or hands; likewise, all germ carriers (typhoid, paratyphoid, dysentery and cholera). Similar restrictions guard the production and marketing of milk. If anything, they are even more strict.

An Antituberculosis Film

Utilizing the funds raised through subscriptions collected by the Green Cross of Groningen, the central antituberculosis commission has had a film prepared to enlighten the people in regard to tuberculosis. The film does not inspire fear but awakens rather the hope of recovery owing to the treatment made available through the antituberculosis organizations. The scene opens with a shoemaker working in his shop. He begins to observe symptoms of tuberculosis but refuses to pay a visit to the antituberculosis dispensary. The spectator is brought face to face with the dangers of crowded dwellings and sees that infection, once in the home, is bound to contaminate the children. One day the shoemaker happens to enter the antituberculosis museum, where a physician explains to him the pathology and the dangers of tuberculosis. He comes out an enlightened man. Shortly his improvement as the result of the good care he receives is noticeable. There pass successively across the screen views of attractive sanatoriums and beautiful parks for convalescents. Finally, after leaving the sanatorium, almost fully restored to health, the shoemaker is seen working at his trade in the open air, in a postsanatorial therapeutic center. In the meantime, a nurse has taken care of his children, having taken them to a maritime colony in the country. They, also, return much improved in health by their outing.

Life Expectancy of Physicians

In an article in the *Nederlandsch Tijdschrift voor Geneeskunde,* Dr. De Wilde gives some of the results of his researches on the life expectancy of physicians. Greene in his book "Examination for Life Insurance" makes the statement: "Judged strictly by mortality tables, the doctor would be a poor risk." De Wilde's researches cover 2,500 physicians who have died since 1861. The average age at which the group began to practice was found to be 25. The average age at which death occurred was 59.6, whereas the average age of death of the male population during the same period was 64.8. The percentage of physicians dying in the various decades is shown in the subjoined table.

Percentage of Physicians Dying at Various Ages

Age	Percentage
From 25 to 35	8.06
From 35 to 45	9.5
From 45 to 55	14.88
From 55 to 65	20.38
From 65 to 75	24.28
From 75 to 85	16.78

BERLIN

(From Our Regular Correspondent)

Feb. 20, 1926.

Tuberculosis Mortality Among Miners of the Ruhr Region

The tuberculosis mortality of the miners of the Ruhr region before the war was lower than in almost all other dust-producing industrial occupations, and lower than the average mortality for Germany as a whole. This is partly explained by the fact that in the mines more often than in other industries, workmen whose physical condition was below par were excluded. Another circumstance that contributes to the low mortality among miners is the earlier age at which they may be put on the pension list for invalidism or permanent total disability. Dr. Grünewald of Dortmund has pointed out that among underground workmen droplet infection can scarcely occur; furthermore, sputum expectorated on coal, owing to the damp coal dust, is not likely to be carried in floating dust particles. Many believe another factor is that, owing to the high wages that miners received before the war when compared with the lower price that they paid for food, they were able to supply themselves with especially good food. Soon after the beginning of the war, the food supply became deficient and prophylactic measures came to be neglected. These circumstances exerted an unfavorable influence on the tuberculosis mortality of the whole population, including the miners. The adjoining table shows the mortality from pulmonary tuberculosis in the mining industries of the Ruhr region in Prussia and in Germany in the period from 1910 to 1924.

Mortality per 10,000 from Pulmonary Tuberculosis Among:

	Members of the *Ruhr Mining* Association	*Inhabitants of* Prussia	*Inhabitants of* Germany
1910	7.86	13.4	13.0
1911	7.39	13.4	13.6
1912	6.40	12.9	13.1
1913	6.16	11.9	12.1
1914	7.29	12.2	12.2
1915	9.59	12.8	12.8
1916	11.45	13.9	13.9
1917	16.82	18.4	18.0
1918	21.68	20.9	20.2
1919	17.34	18.8	18.2
1920	10.22	13.3	13.0
1921	9.19	11.8	11.5
1922	11.23	12.4	12.0
1923	14.99	....	....
1924	9.26	....	....

In the main, the tuberculosis mortality among the Ruhr miners before, during and since the war has been subject to the same fluctuations as among the remaining population. With the exception of the years 1922 and 1923, which correspond with the period of depreciation of the currency and the passive resistance in the Ruhr during which wages and the cost of living did not stand in the proper relation, it will be seen that the mortality rate of the Ruhr miners is approaching the prewar figure. In connection with the high mortality rate during the war years, it must be recalled that the healthiest of the miners had been drafted into the army. Their places had been taken, for the most part, by old or youthful persons, and, in addition, the medical examinations for admission to the mines were not so strictly carried out as before the war. The fact that the rate in 1924 is not as low as that of the prewar period is partly because the weaker workmen selected during the war years as a rule remained in the mines. Also, a shortening of the shifts has necessitated a larger number of workmen, and with the increased demand for men the vigilance of the examiners may have relaxed somewhat. Other factors are the large number of refugees from the war zones who have been given employment and the bad housing situation. In spite of these adverse conditions, the percentage of deaths from pulmonary tuberculosis among the miners of the Ruhr region is considerably below the average for the country as a whole. No doubt the general improvement in wages and in living conditions exerted a favorable influence on the mortality rate for 1924.

Death of Prof. J. Israel

Prof. J. Israel, the well known surgeon, died, February 20, at the age of 78. Up to a few weeks before his death he performed difficult operations. The apparent cause of death was a latent gastric carcinoma. In spite of his advanced age, he enjoyed unusual health and vigor up to the beginning of his illness. His renewed activity in recent years was, to be sure, forced upon him. With the completion of his seventieth year he had given up the directorship of the surgical department of the Jewish Hospital, and it was doubtless his intention soon to retire from private practice. But the financial crisis brought on by inflation of the currency left him, like many others, without adequate means of support, so that he was compelled to continue his professional work. He was a remarkable diagnostician and surgical technician. Israel was indebted for diagnostic ability to his teachers Traube and Langenbeck. He was Langenbeck's assistant when the latter was in charge of the surgical department of the Jewish Hospital. It was owing to Langenbeck's recommendation that Israel became his successor. Although Israel never formally assumed an academic career, he nevertheless became the teacher of many physicians in this and foreign countries, which circumstance led to his being frequently chosen by foreign physicians to serve as consultant. His fame as an investigator was based on two main achievements: his discovery of the rôle of the Actinomyces parasitic fungus in human pathology, which was first set forth in a monograph appearing in 1885, and his epoch-making articles on kidney surgery. Especially important was his demonstration that tuberculosis of the kidney in many—possibly most—cases is primary and is not due to the upward trend of a bladder infection, as was formerly assumed. This demonstration opened up the possibility of eliminating kidney tuberculosis by extirpation of the diseased organ. His monograph, published in 1894, on "Experiences with Kidney Surgery" occasioned something of a sensation. In 1901, he published an enlarged edition entitled "Clinical Surgery of Kidney Diseases." Numerous further scientific treatises included all fields of surgery. His plastic operations were especially significant. In Berlin society, and especially in medical circles, he held a high position. He was vice chairman of the Berliner Medizinische Gesellschaft, and an honorary member of the Deutsche Gesellschaft für Urologie and of several foreign surgical societies.

Marriages

Arthur F. Smith to Miss Isabelle Amundson, both of Milford, Iowa, January 6.

Dennis H. Kelly, Clinton, Iowa, to Miss Ailen Carney of Grinnell, January 4.

Isaac J. Townes, Madisonville, Ky., to Miss Laura E. Hoffman of Mayfield, March 11.

Deaths

Harry Merriman Steele, New Haven, Conn.; Johns Hopkins University Medical Department, Baltimore, 1902; past president of the New Haven County Medical Society; member of the Connecticut State Medical Society, and the New England Pediatric Society; assistant in pediatrics, University and Bellevue Hospital Medical College, 1902-1904; clinical professor of pediatrics, Yale University School of Medicine, and for several years instructor in pediatrics and assistant in pathology; on the staffs of the Charlotte Hungerford Hospital, Torrington, and St. Raphael's Hospital, New Haven; aged 54; died, March 18, of lobar pneumonia.

Henry Fauntleroy Harris, Atlanta, Ga.; Atlanta Medical College, 1889; Jefferson Medical College of Philadelphia, 1890; member of the Medical Association of Georgia, and the American Association of Pathologists and Bacteriologists; professor of chemistry, Southern Medical College, 1892-1896, associate professor of pathology, Jefferson Medical College, 1896-1901, and professor of pathology and bacteriology, Atlanta College of Physicians and Surgeons, 1901-1910; formerly secretary of the Georgia State Board of Health; aged 59; died, March 18, at the Jefferson Hospital, Philadelphia, of paralysis.

George Washington McDowell, New York; New York Homeopathic Medical College, 1886; emeritus professor of ophthalmology, otology and rhinology at his alma mater; member of the New York Academy of Pathological Science; on the staffs of the Flower Hospital, New York Ophthalmic and St. Gregory's hospitals, Laura Franklin Free Hospital for Children, Protestant Half-Orphan Asylum and the Methodist Episcopal Church Home; aged 65; died, March 16, at New Rochelle, N. Y.

Howard A. Hellyer, Penns Park, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1868; member of the Medical Society of the State of Pennsylvania; past president of the Bucks County Medical Society; secretary of the county school board since 1885; aged 80; died, March 12, at the Samaritan Hospital, Philadelphia, following a long illness.

Thomas J. W. Burgess, Montreal, Que., Canada; University of Toronto (Ont.) Faculty of Medicine, 1870; formerly professor of mental diseases, McGill University Faculty of Medicine; at one time superintendent of the Protestant Hospital for the Insane; member of the American Psychiatric Association; aged 76; died, January 18.

George Minot Garland ⊕ Wellesley Farms, Mass.; Medical School of Harvard University, Boston, 1874; assistant in physiology, 1877-1881, and assistant and instructor in clinical medicine, 1881-1892, at his alma mater; formerly on the staff of the Massachusetts General Hospital, Boston; aged 77; died, March 2.

Harry J. Hornbogen ⊕ Marquette, Mich.; College of Physicians and Surgeons, Chicago, 1894; secretary of the Marquette County Medical Society; member of the board of education; formerly on the staff of St. Luke's Hospital; aged 54; died, March 17, at Hollywood, Calif., of heart disease.

Henry Morton Hall, Cedartown, Ga.; University of Georgia Medical Department, Augusta, 1899; member of the Medical Association of Georgia; part owner of the Hall-Chaudron Hospital; formerly mayor of Cedartown; served during the World War; aged 56; died, March 14, of myocarditis.

Thomas John Sullivan, Jr. ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1915; member of the Chicago Orthopedic Club; on the staff of the Mercy Hospital; served during the World War; aged 36; died, March 23, of chronic nephritis.

Joseph Alphonse Kene ⊕ Brooklyn; Medical Department of the University of the City of New York, 1878; chief medical examiner of the Municipal Civil Service Commission since 1898; member of the Brooklyn Neurological Society; aged 69; died, March 11, of heart disease.

Harry Lavelle Murphy, Pittsburgh; Georgetown University School of Medicine, Washington, D. C., 1912; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 38; died, February 10, at the Southside Hospital, of pneumonia.

Charles A. McCollum, Pasadena, Calif.; Rush Medical College, Chicago, 1868; formerly connected with the Medical Department Hamline University, Minneapolis; at one time on the staff of St. Mary's Hospital, Minneapolis; aged 78; died, January 22.

Virgil Maro Dow Marcy, Jr. ⊕ Cape May, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1900; formerly president of the board of health and board of education; served during the World War; aged 47; died, March 8.

J. Brown Wallace ⊕ Tampa, Fla.; University of Maryland School of Medicine, Baltimore, 1897; served in the M. C., U. S. Army, during the World War; on the staff of the Bayside Hospital; aged 52; died, Dec. 31, 1925, of pneumonia.

Frederick L. Wakeham, New York; Medical Department of Columbia College, New York, 1892; formerly on the staffs of the Mount Sinai and Sydenham hospitals; aged 55; died, March 4, at New Rochelle, following a long illness.

Wyclif Kerr Curtis, Midland, Texas; Jefferson Medical College of Philadelphia, 1878; member of the State Medical Association of Texas; county health officer; aged 73; died, February 27, at a hospital in El Paso, of pneumonia.

William J. Burd ⊕ Belvidere, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1889; formerly president and secretary of the Warren County Medical Society; aged 60; died, March 5, of heart disease.

Charles Hervey Bailey, New York; Medical School of Harvard University, Boston, 1910; member of the Medical Society of the State of New York, and the New York Pathological Society; aged 44; died, March 1.

Christian R. Scheller ⊕ Hagerstown, Md.; Jefferson Medical College of Philadelphia, 1883; formerly president of the board of health; for several years county and city health officer; aged 64; died, March 5.

Thomas Henry Welsch, Hannibal, Mo.; Barnes Medical College, St. Louis, 1904; aged 43; was killed, March 1, near Wentzville when the automobile in which he was driving went over an embankment.

John Percival Hewson, Orange, Texas; University of Pennsylvania School of Medicine, Philadelphia, 1913; aged 38; died, February 27, at St. Joseph's Hospital, Denver, of pulmonary tuberculosis.

Alva Rufus Hull, Nampa, Idaho; Northwestern University Medical School, Chicago, 1898; served during the World War; aged 53; died, March 10, of a gunshot wound, presumably self-inflicted.

John Warren Holt, Eminence, Ky.; Louisville Medical College, 1897; member of the Kentucky State Medical Association; aged 54; was found dead in bed, March 2, of chloroform poisoning.

George Wicks Spencer ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1892; formerly associate professor of surgery at his alma mater; aged 55; died, March 7, of uremia.

Dewees A. W. Huebner, Fern Glen, Pa.; Jefferson Medical College of Philadelphia, 1886; member of the Medical Society of the State of Pennsylvania; aged 62; died, Dec. 1, 1925.

Joseph Merrell Hamblin, San Francisco; California Eclectic Medical College, Los Angeles, 1918; aged 32; died, January 5, at the San Francisco Hospital, of chronic bronchitis.

Joseph L. Isenberg, Williamsburg, Pa.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; aged 57; died, Nov. 17, 1925.

James Crowe Burdett, Evelyn, La.; Memphis Hospital Medical College, 1905; served during the World War; aged 49; died, February 16, at the Mansfield (La.) Sanitarium.

Charles Augustus Adams, Des Moines; Meharry Medical College, Nashville, Tenn., 1906; member of the Iowa State Medical Society; aged 48; died, January 26.

William L. Newton, Camden, Ark.; Memphis Hospital Medical College, 1899; formerly postmaster; aged 50; died, February 26, of heart disease.

⊕ Indicates "Fellow" of the American Medical Association.

Theophilus J. Langlois, Wyandotte, Mich.; Detroit Medical College, 1871; health officer of Wyandotte for forty years; aged 86; died, March 3, of hypostatic pneumonia and senility.

Henry Croskey, Kansas City, Mo.; Hahnemann Medical College of Philadelphia, 1878; aged 77; died, February 19, at St. Luke's Hospital, of cerebral hemorrhage.

Amos Bryan Krebs ⊕ Bolivar, Pa.; Cincinnati College of Medicine and Surgery, 1886; aged '62; died, February 10, at the Memorial Hospital, Johnstown, of diabetes.

Earl Percy Cushman, Claremont, N. H.; University of Vermont College of Medicine, Burlington, 1900; served during the World War; aged 52; died, February 23.

Henry W. Kriege, St. Louis; St. Louis Medical College, 1885; Homeopathic Medical College of Missouri, St. Louis, 1888; aged 67; died, February 27, of anemia.

William Stump, Emmorton, Md.; University of Pennsylvania School of Medicine, Philadelphia, 1895; aged 57; died, February 3, of angina pectoris.

George Stephen Mikkelsen ⊕ Kewanee, Ill.; Chicago College of Medicine and Surgery, 1907; aged 43; died, March 9, at a hospital in Chicago.

Robert Stanley Minnes, Ottawa, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1893; aged 55; died, Dec. 27, 1925.

John Calvin Rush, Eatontown, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1896; aged 71; died suddenly, March 3.

Bryan DeForest Sheedy, New York; Medical Department of the University of the City of New York, 1885; aged 61; died, March 5.

Jonathan McCully, Cedar Springs, Ont., Canada; Victoria University Medical Department, Toronto, 1866; aged 91; died, Dec. 22, 1925.

Byron A. Smith, Erie, Pa. (licensed, Pennsylvania, 1881); formerly a druggist; aged 83; died, February 25, following a long illness.

Thomas Walker, St. John, N. B., Canada; L.R.C.S., Edinburgh, 1863; University of Edinburgh, 1863; aged 85; died, Dec. 25, 1925.

E. L. Crumpler, Merry Hill, N. C.; Medical College of Virginia, Richmond, 1893; died, February 20, of influenza and asthma.

John L. Cassilly, St. Louis; Missouri Medical College, St. Louis, 1867; Civil War veteran; aged 81; died, February 21, of senility.

Robert Gerstell, Keyser, W. Va.; University of Maryland School of Medicine, Baltimore, 1873; aged 76; died in February.

Neville James Lindsay, Calgary, Alta., Canada; Trinity Medical College, Toronto, Ont., 1874; aged 80; died, Dec. 17, 1925.

Charles Sherman Jewett ⊕ Buffalo; Medical Department of Columbia College, New York, 1890; aged 60; died, Nov. 5, 1925.

James Neeper Richards, Fallsington, Pa.; Bellevue Hospital Medical College, New York, 1873; aged 76; died, January 19.

John Benson, Colfax, Wash. (licensed, Washington, 1885); for many years county health officer; aged 76; died, January 27.

John Charles C. Grasett, Simcoe, Ont., Canada; Trinity Medical College, Toronto, 1887; aged 63; died, Dec. 14, 1925.

George A. Yates, Cleveland; University of Nebraska College of Medicine, Omaha, 1889; aged 65; died in February.

Christopher C. D'Armond, Knoxville, Tenn.; University of Louisville School of Medicine, 1884; aged 78; died recently.

Hiram Wigle, Wiarton, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1875; died, January 4.

Aaron Rivkees ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1913; aged 47; died, February 10.

Caleb Blyholder, Pittsburgh; Jefferson Medical College of Philadelphia, 1873; aged 83; died, February 24.

James McComb, Lebanon, Mo.; Jefferson Medical College of Philadelphia, 1865; aged 93; died, March 6.

Frederick Ernest Schmidt, Muscatine, Iowa; Keokuk Medical College, 1891; aged 56; died, January 8.

Edward Reese Cook, Vicksburg, Miss.; St. Louis Medical College, 1877; aged 69; died, February 10.

George O. Baxter, St. John, N. B., Canada; Detroit Medical College, 1885; died in December, 1925.

The Propaganda for Reform

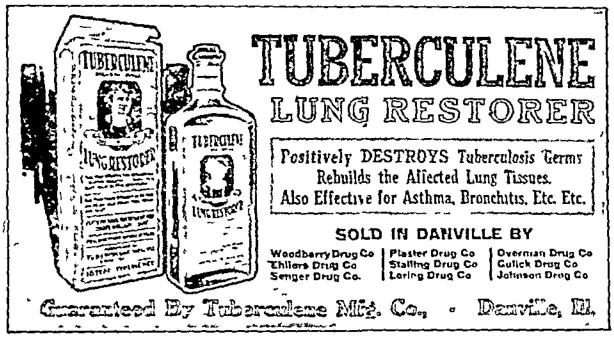
In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

TUBERCULENE

A Fraudulent Consumption Cure Debarred from the Mails

For over a year a rather self-evident fraud has been exploited from Danville, Ill., under the trade name Tuberculene Manufacturing Co., by one Mrs. G. J. Murrman, who sold "Tuberculene," a "lung restorer." The price was $3 for fifteen days' treatment. The preparation was put on the market so crudely that it not only obviously violated the federal Food and Drugs Act but its sale constituted fraudulent use of the United States mails. March 8, 1926, Postmaster General Harry S. New, on the recommendation of Judge Horace J. Donnelly, Solicitor of the Post Office Department, issued a fraud order against the Tuberculene Manufacturing Co. and its officers and agents at Danville, Ill.

Judge Donnelly's memorandum to the Postmaster General describes the case against this swindle. December 15, 1925, the Tuberculene Manufacturing Co. was called on to show cause why a fraud order should not be issued against it. December 21, J. J. Carter, an attorney of Danville, Ill., filed a brief on behalf of Mrs. G J. Murrman



TUBERCULENE
LUNG RESTORER

Positively DESTROYS Tuberculosis Germs
Rebuilds the Affected Lung Tissues.
Also Effective for Asthma, Bronchitis, Etc. Etc.

SOLD IN DANVILLE BY

Woodberry Drug Co	Plaster Drug Co	Overman Drug Co
Ehlers Drug Co	Stalling Drug Co	Gulick Drug Co
Senger Drug Co.	Loring Drug Co	Johnson Drug Co

Guaranteed By Tuberculene Mfg. Co., • Danville, Ill.

The Solicitor's memorandum declares that Mrs. Murrman is an uneducated, middle-aged woman, who was exploiting Tuberculene as a cure for tuberculosis and other conditions. Her method was to insert in newspapers circulating through the mails in the vicinity of Danville an advertisement reading as follows:

TUBERCULENE
Destroys All T. B. Germs.
Heals Up the Lungs.
Why Put Up with T. B., Asthma, Flu,
Bronchitis, Coughs or Colds of Any Kind?
Tuberculene Gets Rid of These Ailments
Lung Restorer and Germ Destroyer.
Guaranteed If Taken According to Directions.

No individual with intelligence enough to publish a newspaper could, in this age and day, believe that this advertisement is bona fide. One of the main reasons that the mail-order medical quack plies his trade is that there are newspapers or magazines that will accept his advertising and become the intermediary for the contact between the swindler and the swindled.

The postal authorities, in investigating Tuberculene, had one of the inspectors enter into test correspondence with the Tuberculene Manufacturing Co. for the purpose of obtaining information respecting the representations under which Tuberculene was sold through the mails. The Tuberculene concern in replying to the request for information regarding the product wrote that Tuberculene would do all that it claimed, and stated that there were a number of tuberculous patients who had been cured by Tuberculene and that some of them were living in Danville. Another letter was written to the company, asking that the medicine be sent provided it would effect a cure of tuberculosis. A bottle of the stuff was thereupon forwarded, parcel post, C. O. D., $3.

Tuberculene was a mixture of creosote, rock candy syrup, glycerin, syrup of wild cherry and coloring matter. The government thereupon called on Dr. Lyman F. Kebler, who is in charge of special collaborative investigations, Bureau of Chemistry, U. S. Department of Agriculture, for an opinion regarding this product and the claims made for it. Dr. Kebler, who was formerly connected with a sanatorium for the treatment of tuberculosis, explained, of course, that no such mixture as this had any curative value in consumption. He pointed out, too, that the use of such a nostrum by the tuberculous would, in all probability, only serve to cause the unfortunate victim to lose precious time in his fight for life. He explained that creosote preparations had long been used in the treatment of certain symptoms in cases of pulmonary tuberculosis, but that it has definitely been established that they do not destroy the tubercle bacilli. He declared that the claim made by Mrs. Murrman that Tuberculene would "destroy all T. B. germs" was false and fraudulent.

The Solicitor's memorandum shows that Mrs. Murrman has no knowledge of medicine, but on the contrary "is shown by her conversation and letters to be very ignorant." Although the active promotion and the sale of Tuberculene was not begun until January, 1925, Mrs. Murrman advertised "18 yrs. Experience." In view of the evidence Judge Donnelly declared the business a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and recommended the issuance of a fraud order.

Correspondence

DIABETES MELLITUS AND CHRONIC ARTHRITIS

To the Editor:—The article on this subject (The Journal, February 20, p. 535) suggests a note on my personal experience with diabetes and arthritis.

In July, 1923, after twenty years of careful, conventional antidiabetic dieting, I had a sudden acute attack of sciatica in the right hip and leg. My physician immediately began the use of insulin with a weighed diet. There was no other treatment. After ten weeks of helplessness in bed followed by four months spent in getting the muscles back to normal, complete recovery was secured, except for a slight numbness in the right big toe. The net stripped weight, which had dropped during five years to 149 pounds (68 Kg.), began to increase. Within a year it went to its former 187 (85 Kg.), the right figure for my height of 6 feet 1 inch (185 cm.). It stays at 187. Four years before the attack of sciatica, both tonsils were removed because they were in poor condition. There had been no rheumatism or arthritis at any age before the sciatica. Insulin is continued at 50 units twice daily before each of the two meals, 100 units every twenty-four hours. The diet is whatever I like, provided it is kept within the limits of the insulin. The food is not weighed, but the amounts are those indicated by experience, checked by daily tests with Benedict solution. Generous quantities of milk, butter, cheese and celery, and bulky, raw foods are eaten.

On four occasions, following neglect of control by the Benedict tests and consequent overload of blood sugar, a troublesome attack of arthritis has occurred. Each attack was prevented from becoming severe by cutting the diet down to Benedict sugar free condition. But as the arthritis remained rather constant, the experiment was tried of taking 20 units of insulin at 9 p. m. in order to test the effect of reduced blood sugar during the hours of sleep. As a precaution, a quantity of lump sugar was placed beside the bed so that if disagreeable symptoms arose from low blood sugar the condition could be promptly corrected. The insulin was injected two hours before the time of falling asleep, as a further safeguard. The result was the one hoped for. The arthritis ceased and cleared away completely as the result of taking the insulin on two successive evenings. After several months there was another attack at another location, when the blood sugar had been allowed to become excessive through neglect of control by Benedict tests. The right leg and hip were never attacked. The left hand, jaws, and twice the shoulders were the locations. Each was cleared in two days.

I am a retired chemical engineer, and not a physician; by good fortune, thirty-five years ago, I made the professional acquaintance of the late Dr. Henry L. Elsner of Syracuse, who taught me the habit of birthday long life health examinations. They disclosed the diabetic tendency and established its control by careful diet. The use of insulin since 1923 has brought normal health, as indicated by restored weight and energy of body and mind.

H. W. Jordan, Syracuse, N. Y.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SALIVATION AFTER MERCURY

To the Editor:—Please discuss the cause of salivation after the administration of calomel or other forms of mercury. I have not had trouble with salivation myself in treating patients with calomel, but the public frequently charges that a physician gave calomel and did not tell the patient what he was giving and left no caution about giving acids. Then after the patient partook of lemonade or vinegar or acid fruits or pickles, salivation resulted. In a case of typhoid, salivation was said to be the cause of death. Do sour things really have anything to do with it? Isn't it the change of the mild mercurous chloride into the corrosive mercuric or other form resulting from the addition of chlorine taken from another group—HCl or NaCl? Kindly discuss the cause, treatment and prevention of salivation. In the treatment of syphilis the physiologic effect of mercury or beginning salivation is often attained. Withdrawal of the mercury and elimination with the use of atropine and potassium chlorate in the mouth corrects it. Therefore, how could such disastrous results as alleged occur from calomel in a case of typhoid or any other condition? Kindly omit name. M.D., Kansas.

Answer.—The mechanism of the production of mercurial stomatitis is not perfectly understood. There are chiefly two theories that deserve recognition in accounting for it. According to one, it is due to the irritation produced by the mercury eliminated in the saliva. Variability in degree of elimination by this channel, which has been demonstrated to occur, would account for variation in susceptibility. There are, however, a number of peculiarities of this condition that cannot well be accounted for in this manner. According to the other theory, it is the hydrogen sulphide produced by bacterial decomposition of putrefying organic matter, that reacts with the mercury ion circulating in the capillaries, causing its precipitation and accumulation at such areas in harmful quantities. This theory would explain the reason for the special tendency of inflammation and even necrosis to localize itself at the two ends of the alimentary tract, the mouth and the colon; also why a clean mouth is much less liable to mercurial stomatitis than one that harbors putrefying material. As such matter accumulates between the teeth and in the cavities of decaying teeth, it explains the marked immunity of the edentulous, including infants, to this disturbance. That the theory incriminating hydrogen sulphide with this occurrence does not offer an altogether satisfactory explanation is shown by the fact that stomatitis may not occur even though the mouth is foul and that it may occur, though rarely, in a patient with a clean mouth. That the presence of certain bacteria plays an important rôle in this condition cannot be doubted.

A foul condition of the mouth, together possibly with poor elimination by other channels and a general lowering of cell nutrition, might account for more disastrous results from calomel in a typhoid fever patient than would occur ordinarily.

Why acidulous fluids, such as lemonade or vinegar, should be charged with a tendency to produce ptyalism is not easy to comprehend, and that this is a fact may well be doubted. The true acid (hydrogen ion concentration) of these is very low; and, as is well known, the acidity even of the gastric juice, which is much greater, does not activate calomel, as this does not become active until it reaches the intestine.

The prevention of salivation, as will be readily understood from what has just been said, depends not only on limiting the dose of the mercurial to the capacity of the organism, but also on keeping the mouth in a perfectly hygienic condition, including whatever dental care may be required. The use of a mouth wash and soft tooth brush after each meal should be insisted on. In addition, smoking is inadvisable.

In the treatment of the condition, besides stopping immediately the introduction of the mercurial, steps should be taken to favor its elimination by other channels. Sodium thiosulphate might be given for its alleged antidotal action.

As local treatment, the use of potassium chlorate in saturated solution as a mouth wash is too well known to require detailed discussion. If, however, there is necrotic material in the mouth, hydrogen peroxide, 1 part, diluted with warm water, 2 or 3 parts, is of advantage. Marked fetor would require the frequent use of a rose or port wine color solution of potassium permanganate. When the necrotic material has been shed and ulcers are left, full healing may be expedited by the occasional application of silver nitrate. The pain on eating may be considerably relieved by preliminary use of a local anesthetic, such as ethyl aminobenzoate (benzocaine).

THE ZOALITE LAMP

To the Editor:—I am writing to seek information relative to a therapeutic lamp called the Zoalite, which I think is on the general commercial market. What I wish to know is whether you can tell us the percentage of infra-red given off from this lamp and what other rays are given off from it?

A. F. TYLER, M.D., Omaha.

ANSWER.—The Zoalite is a device for producing radiant heat for therapeutic purposes. The heat is produced by a "resistor," which is heated by an electric current. This "resistor" is similar in composition to the "resistor" used in some heaters sold for domestic purposes.

The radiant energy emitted by this heating unit is not unlike the radiant energy produced by any incandescent body, such for example as a bar of hot iron or the filament of a tungsten lamp.

The therapeutic value of the Zoalite is precisely that of other sources of radiant heat.

INFANT FEEDING

To the Editor:—This letter is both an inquiry and, perchance, a warning. Recently our local clinical club in a city of 20,000 held a clinic at our local hospital. One of the leading pediatricians of our country spoke. This particular clinic was a great success. But I am wondering about some of the statements made: "Condensed milk or dried milk is the best infant food aside from mother's milk." "This case [swollen abdomen, marasmus, malnutrition] is intestinal indigestion, and tuberculous peritonitis can be ruled out because of the age" (2 years). Are these statements universally accepted, along with the one that "starch is well handled by infants after the fourth month"? We, in the country, work under a great handicap. We have no great hospitals at our front door; but we do visit the larger clinics with more frequency, I believe, than is the custom among the rank and file in the large city. We do not want skim milk when we invite a leader to come to us. We are able to digest red meat, and that is what we desire. This letter sounds harsh, as I reread it. That is not my intent. I do wish, however, that the men who come out to us could remember that we, like themselves, are physicians. Learning is available to all men. Please use initials only.

R. E. S., Vermont.

ANSWER.—Cow's milk dilutions with carbohydrates added are the food of choice for infant feeding when breast milk is not available. There are few infants who will not thrive on such fresh, clean cow's milk mixtures throughout most of the year even though we have a good quality of milk. The exceptional baby may not be able to take fresh cow's milk, but these are few. If good milk is not available, the dried milks should be given consideration. The same may be said when the child is traveling or is taken for short visits away from its regular diet. Dextri-Maltose, Mellin's Food, and Horlick's Malt Food have practically the same ingredients except for a difference in percentages.

Tuberculous peritonitis is more common after the second year than before; acute miliary tuberculosis involving the peritoneum is more frequent under 2 years of age.

Well cooked starch may be added to the milk mixtures after the sixth week of life.

All of the points covered in this answer, with the exception of that on tuberculous peritonitis, are contained in "Infant Feeding," published by the American Medical Association.

ACCESSORY PANCREAS

To the Editor:—I wish to know whether it will be possible to find out if the case of de Jong of accessory pancreas at the pylorus occurred in an infant or adult, and if the stenosis was congenital. The case is referred to in an abstract in THE JOURNAL, July 10, 1920, page 141.

KELLY HALE, M.D., Wilmington, Ohio.

ANSWER.—De Jong's case was published in German in *Virchows Archiv* **223**:220, 1917, and in the *Nederlandsch Tijdschrift voor Geneeskunde* **2**:2372, 1915. The patient was a woman, aged 38, who for eight years had been having symptoms from the stomach, especially spasms of severe pain, relieved by eating; there was no vomiting. Laparotomy on the diagnosis of duodenal ulcer revealed a small tumor, the size of a pea, on the lesser curvature, close to the pylorus, which it partially obstructed. The tumor was excised, completely curing the patient. The tumor proved to be entirely normal pancreas tissue, with normal Langerhans' islands; merely the abnormal location had entailed the severe symptoms. The article is headed "Benign Tumors at the Pylorus," and describes three other cases of hypertrophy with more or less stenosis of the pylorus, caused by simple proliferation of apparently normal glands. There were no signs of inflammation in any of the cases and nothing to suggest malignant disease. The article by Nieuwenhuijse, in which de Jong was mentioned, is an exhaustive study of aberrant pancreas tissue and why it is so often associated with diverticulum formation in the lower portion of the small intestine (seven authors are cited who have published such) but so rarely in the duodenum and never in the stomach. Scagliosi found pancreas tissue in the wall of a duodenal ulcer in two cases. These tumors are always small and benign, according to six authors cited. Saltykow asserts that all carcinoid bowel tumors are due to aberrant pancreas tissue, but Nieuwenhuijse's study of five cases of accessory pancreas (one found at necropsy of a woman, aged 75) failed to reveal any suggestion of malignant disease, and Scagliosi is the only writer who has mentioned such.

NONSPECIFIC PROTEIN IN PSORIASIS

To the Editor:—What are the indications for milk (protein) hypodermic injections? What is the technic for giving milk injections (hypodermic)? Are they indicated or have they been used in the treatment of psoriasis? If so, with what success?

F. E. PERKINS, M.D., Watertown, N. Y.

ANSWER.—Injections of milk protein should be intramuscular, not hypodermic. They have been used in conditions in which it is desired to stimulate resistance to disease by causing a mild reaction to nonspecific proteins. Injections of milk protein have been used in a host of conditions, but this use is not supported by controlled clinical evidence from reputable observers. The technic is that of intramuscular injection. The patient should be face downward on the table with the arms hanging over the sides of the table to aid relaxation. The toes should be directed inward, pigeon toed, to relax the gluteal muscles. One hand of the operator draws down the muscles toward the patient's feet and the other plunges the needle into the buttock at an angle of 20 degrees from vertical (toward the patient's feet) and slightly inward (toward the median line). The point of entrance should be near the lower, inner angle of the outer upper quadrant of the buttock. The needle should be buried to the depth of from 1 to 2 inches in adults, depending on the size of the buttock. The downward pressure on the buttock is then relaxed. If no blood flows from the needle, the syringe, previously filled, is attached, and back traction made for several seconds, at least ten. If no blood appears, the injection is made slowly. One should press with a sterile sponge at the point of entrance of the needle, and withdraw the needle, then massage gently for several minutes. The patient should remain in position for a few minutes after the injection is finished.

USE OF ANTIGONOCOCCAL VACCINE

To the Editor:—Is the injection of bacterins (Neisser) now used extensively? Please use initials.

D. E. S., Alaska.

ANSWER.—It is probable that gonococcus vaccine in some form or other is still used by physicians in the treatment of gonorrhea and its complications. There is no question, however, but that this practice is far less extensive than formerly. The use of gonococcus vaccine for curative treatment appears to be sharing in the decline in popular favor of bacterial vaccines in general. Gonococcus Serum and Gonococcus Vaccine were omitted from New and Nonofficial Remedies because the Council on Pharmacy and Chemistry concluded that there was no evidence to show that these preparations had therapeutic value (Colon Bacillus Vaccine, Gonococcus Serum and Gonococcus Vaccine Omitted from N. N. R., The Journal, Jan. 17, 1925, p. 220).

PRESCRIPTION FOR ALOPECIA

To the Editor.—In The Journal, January 23, in the article on "Technic of Medication," was the formula for a lotion prescribed for alopecia. I have asked at a local druggist's to have this made up, and the question arose as to whether the amount of tincture of cantharides was correctly written or not Equal parts of tincture of cantharides, tincture of capsicum and compound spirit of myrcia was the prescription given. Will you kindly advise me? Pauline L. Packard, Ashland, N. H.

Answer.—The quantities in the "hair tonic," namely, equal parts of tincture of cantharides, tincture of capsicum, and compound spirit of myrcia are correct. A few drops of it rubbed into the scalp every day does not produce rubefaction.

GOAT SERUM

To the Editor —I am much interested in your statement, "In some experiments it has been found that goat serum in certain cases may be quite toxic." Can you give me reference to the experiments together with any further information on the toxic quality of antitoxin derived from goat serum when concentrated and added to diphtheria toxin for use in immunizing against diphtheria?

Millard Knowlton, M D , Hartford, Conn.

Answer.—So far as known, there are no published observations on the toxicity of concentrated antidiphtheria goat serum used in connection with diphtheria toxin. There are observations, however, showing that goat serum may be toxic. Thus, Tunnicliff (Prevention of Measles by Immune Goat Serum, (*J. Infect. Dis.* **38**:48 [Jan] 1926) found that the serum of one goat was toxic for nearly all the persons into whom it was injected; after standing eight months, however, the toxic action seemed to have been lost. The point is that the general assumption of the harmlessness of goat serum probably is not in accord with the real facts in the case. In the meantime this discussion is largely academic in interest because at present there is no goat antitoxin generally available.

TECHNIC OF THERAPY

To the Editor —Kindly advise as to the usual procedure in giving the following by intramuscular injection; i e , as to frequency: 1. Iron and ammonium citrate, $\frac{3}{4}$ grain; sodium arsenate, $\frac{1}{30}$ grain, in secondary anemia 2 One cc. ampules of extract of corpus luteum for relief of symptoms at menopause. How many ampules are considered a course? What is the number of courses usually necessary and the length of rest between them, if any? H. B. Chapin, M D., Torrington, Conn.

Answer.—1. Iron and ammonium citrate with arsenic is injected intragluteally daily or every other day, usually in gradually ascending and then descending dosage from 0 01 up to 0 1 Gm. of the iron salt. The course should be extended for at least six weeks. A course of one or two weeks' duration usually produces little or no result. If, on the other hand, a six weeks' course has not secured the desired result, further treatment is not likely to be successful. During the first week the dose is gradually increased. It is then maintained at the height secured for three weeks, and then gradually reduced during the succeeding two weeks. Regularity of treatment is essential for good results. While the intramuscular injection of iron has become somewhat popular, there is, as a matter of fact, no good evidence for the use of this procedure rather than the customary oral administration.

2. Reliable experience and knowledge regarding the administration of corpus luteum for the relief of the symptoms of the menopause is lacking. There are, indeed, many good authorities who question the value of this treatment, excepting for the psychic effect. It is pointed out in New and Nonofficial Remedies that there is considerable evidence that the aqueous extracts prepared for hypodermic use are inert.

VACCINATION AND TOXIN-ANTITOXIN

To the Editor —In a child who is to be vaccinated against smallpox and who is also to be given diphtheria toxin antitoxin, does it make any difference as to which of these is given first? Please do not publish my name. M D., Missouri.

Answer —So far as known, it will not make any difference whether vaccination is carried out before or after immunization with diphtheria toxin-antitoxin.

Minnesota: Minneapolis, April 6 8. Apply to Mrs. Martha Lundgren, 734 Lowry Bldg , St Paul

Montana: Helena, April 6 8 Sec., Dr. S. A. Cooney, Helena.

National Board of Medical Examiners: Part I, June 21-23; Part II, June 22 23. All applications should be made on or before May 15. Sec , Dr J. S. Rodman, 1600 Walnut Street, Philadelphia.

Nevada: Carson City, May 3 Sec , Dr. Simon L Lee, Carson City.

New Mexico: Santa Fe, April 12 13. Sec , Dr. W. T. Joyner, Roswell.

Rhode Island: Providence, April 1-2. Sec., Dr. Byrum U. Richards, Providence

Utah: Salt Lake City, April 6. Director, Mr. J. T. Hammond, Salt Lake City.

Arizona January Examination

Dr. W. O. Sweek, secretary of the Arizona Board of Medical Examiners, reports the written examination held at Phoenix, Jan. 5-6, 1926. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Of the 7 candidates examined, 6 passed and 1 failed. One candidate was licensed by reciprocity. The following colleges were *represented:*

College	PASSED	Year Grad.	Per Cent
University of California Medical School		(1925)	85.8
Howard University School of Medicine		(1922)	75
University of Kansas School of Medicine		(1925)	90 4
Tulane University of Louisiana School of Medicine		(1922)	86 7
University of Michigan Medical School		(1923)	85.6
University of Nebraska College of Medicine		(1925)	85 7

College	FAILED	Year Grad.	Per Cent
St Louis College of Physicians and Surgeons		(1910)	*

College	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Texas Department of Medicine		(1922)	Texas

* No grade given.

Rhode Island January Examination

Dr. B. U. Richards, secretary of the Rhode Island Board of Health, reports the written and practical examination held at Providence, Jan. 7-8, 1926. The examination covered 7 subjects and included 70 questions. An average of 80 per cent was required to pass. Seven candidates were examined, all of whom passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Harvard University		(1922) 89 5, (1923)	80
Tufts College Medical School		(1924)	84 5, 87.3, 93 7
Jefferson Medical College of Philadelphia		(1924)	90.3
University of Naples, Italy		(1923)*	83 5

* Verification of graduation not completed by the American Medical Association.

Oregon January Examination

Dr. Urling C. Coe, secretary of the Oregon Board of Medical Examiners, reports the written examination held at Portland, Jan. 5-7, 1926. The examination covered 11 subjects and included 110 questions. An average of 75 per cent in each subject was required to pass. Thirteen candidates were examined, all of whom passed. Four candidates were licensed by reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent
Northwestern University Medical School		(1924) 77 (1925)*	80.6
Rush Medical College		(1921) 77 7 (1925)	77.1
University of Illinois College of Medicine		(1925)	82
University of Louisville School of Medicine		(1925)	78.8
Harvard University		(1921)	94.3

[illegible] College	(1921)	80.3
[illegible] cal School	(1924) 81.4, (1925)	83.1, 84.9
[illegible] College of Med. and Surg.	(1923)	77.3
[illegible] ue, Czechoslovakia	(1921)†	83

College LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Harvard [illegible]	(1923)	New York
Universit [illegible] ool	(1923)	Washington
Jefferson [illegible]	(1906)	Penna.
Vanderbil	(1913)	Texas

* This [illegible] and will receive his M.D. degree on completion of a year's internship in a hospital.

† Verification of graduation not completed by the American Medical Association.

Book Notices

Diseases of Infants and Children. By Henry Dwight Chapin, A.M., M.D., Consulting Physician to the New York Post-Graduate Hospital, and Lawrence Thomas Royster, M.D., Professor of Pediatrics and Head of the Pediatric Department of the University of Virginia. Fifth edition. Cloth. Price, $6. Pp. 633, with 162 illustrations. New York: William Wood & Co., 1925.

This edition is presented to its readers with the collaboration of a new editor. L. T. Royster has succeeded Godfrey Pisek, recently deceased. Portions of the book have been rewritten in the attempt to bring them to date. The introductory chapters on the care and hygiene of children and diseases of the new-born, and the section on growth and development, as well as the succeeding chapters on the examination of the sick child, general therapeutics and suggestions for diagnosis, are well written and contain valuable information. The chapter on the infant from the nutritional standpoint is a suggestive and original treatise, representing the authors' view on the biologic standards of infant feeding. In some of the clinical descriptions the text has suffered somewhat in the attempt to be concise, without being fully descriptive. Necessarily, in a book of this nature and size, details must be omitted. This is notably true in the description of the diseases of the digestive system. In a book on pediatrics, this important subject deserves more space and consideration than is given here. Taken as a whole, however, the book will give the student much of value, and the practitioner important information on diagnosis and treatment.

Grundriss der wissenschaftlichen Anatomie. Zum Gebrauch neben jedem Lehrbuch der Anatomie für studierende und Aerzte. Von Dr. Wilhelm Lubosch, Professor der Anatomie in Würzburg. Paper. Price, 18 marks. Pp. 292, with 66 illustrations. Leipsic: Georg Thieme, 1925.

This represents an attempt of the professor of anatomy at Wurzburg to pass on to others what he has found most satisfactory in his study of anatomy as a science. The desire to understand leads to keen interest in the general principles of all sciences. Few sciences are as well adapted as anatomy to awaken and satisfy that interest, but Lubosch laments that its study is too often made drudgery, and that the student thus loses a great intellectual joy and satisfaction. This satisfaction Lubosch has found in seeing in the living human body the expression of these general principles and a working model of vital processes. He has devoted his lectures on anatomy to an endeavor to set forth these visions, and the book has resulted from the course of lectures. With the love of system that characterizes German professors in their philosophic reviews, he surveys the whole field and sets everything in order. First he considers the relations of this science to others, such as physiology, medicine and philosophy, and then proceeds to a systematization of the individual science, its scope and content. He divides the book into a general section and a special section. The general section includes his conception of living matter, its essence and character. Recognizing the philogenetic kinship of man with other animal forms, he surveys the principles of structure of living animals (especially vertebrates) and the changes that have led to the diversification of their structure. The principles of transformation of which these bodies are expressions are formulated and reviewed. The special section deals with the human body only. With considerations of the normal and the range of variation, with racial anatomy, symmetry and segmentation, it treats of development and the search for its productive causes in experimental embryology. A consideration of the morphology of tissues is followed by a similar study of cells, leading ultimately to an effort to relate cell structure to the colloidal structure of protoplasm. The author does not pretend to cover the great subjects of which he treats, but tries only to sketch in the line along which thought will naturally proceed. He includes references to the literature up to 1924, and has made or borrowed sixty-six figures, mostly schematic, to assist in the presentation of the ideas considered. Many of these were prepared for his lectures. Thoughtful students will welcome this book and others of its kind. It will help toward an understanding of anatomy and morphology, and toward an appreciation of the beauty of general, even if theoretical, explanations of morphologic facts.

Scoliosis. Rotary Lateral Curvature of the Spine. By Samuel Kleinberg, M.D., F.A.C.S., Assistant Surgeon, New York Hospital for Ruptured and Crippled. Cloth. Price, $6. Pp. 311; with 140 illustrations. New York: Paul B. Hoeber, Inc., 1926.

In presenting the subject of scoliosis, the author reviews concisely the knowledge and experiences acquired during the last twenty years, avoiding the theoretical and discussing the practical and useful. The book is written primarily for the orthopedic surgeon, but is of great value to the general practitioner, because it is the latter who sees this type of patient long before the orthopedic surgeon. Much valuable time will be gained if the general practitioner has a working knowledge of the principles of diagnosis and treatment. There are excellent chapters on the anatomic and physiologic aspects of the condition. The author takes exception to the statement of Hibbs, that scoliosis is in the majority of cases a result of infantile paralysis. He is convinced that scoliosis is due to this disease in only a small percentage of cases. The author states how difficult the problem of scoliosis is, and then proceeds to prove how simple it is if his method is followed. He lays much emphasis on potential improvement in a large percentage of cases by corrective plaster-of-paris jackets and gymnastic exercises when correctly and judiciously applied in appropriate cases. In brief, his operative treatment is divided into three parts: the preoperative stage of from four to eight weeks of absolute recumbency on a Whitman frame, the body in extension-traction on the convex frame; the operative stage, consisting of an operation combining features of the Hibbs, Albee and Forbes methods; the postoperative stage of recumbency without apparatus for from seven to ten days, and then a gradual return to the preoperative treatment for eight weeks. After this a plaster jacket is applied and the patient is allowed to stand and go home, returning every two weeks for observation. The jacket remains on at least six months. A roentgenogram is made every month, and after from six to nine months a corset is supplied. The author believes that operation should be restricted to those cases in which there is a progressive increase of deformity irrespective of the etiologic basis of the scoliosis or of the age of the patient. If operation is performed, he advises against corrective exercises. In thirty-one of thirty-three cases, fixation, the object of operation, was obtained; there were two relapses. The book can be recommended highly to the medical student, to the general practitioner and to the orthopedic surgeon.

Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students. By Sir Thomas Lewis, M.D., F.R.S., D.Sc., Consulting Physician to the Ministry of Pensions. Sixth edition. Cloth. Pp. 131, with 55 illustrations. London: Shaw & Sons, Ltd., 1925.

In the minds of most physicians, the name of Sir Thomas Lewis has been intimately associated with electrocardiography and research in connection with heart disease. It is a surprise to some, therefore, to learn that he has written an eminently practical book concerning the commoner irregularities of the heart, and, further, that in this book he purposely avoids reference to the electrocardiograph and only rarely calls in the aid of any other instrument of precision. His aim is, in other words, to discuss these conditions from the noninstrumental standpoint, and to show that they may be recognized and understood by careful observation and logical reasoning if only the fundamental principles of cardiac physiology and pathology have been previously mastered. That he has been successful is proved by the fact that in fifteen years six editions of this book have been called for. In this edition the work has been brought down to date. All that has been said in reviews of previous editions in praise of the lucidity of style, conciseness and forcefulness may be here repeated. The work is written in the first person singular. We have counted the names of but few others in the whole work, incidentally mentioned: Purkinje, Cheyne-Stokes, Adams-Stokes. This means that the work is an individual one, expressing the views of Lewis and Lewis alone. The ego in the book is not, however, offensive, and for the general practitioner it is more useful than if written in a less dogmatic manner. It remains today one of the very best books on this subject, perhaps the very best.

Medical Ophthalmology. By R. Foster Moore, O.B.E., M.A., B.Ch., Assistant Ophthalmic Surgeon, St. Bartholomew's Hospital. Second edition. Cloth. Price, $6. Pp. 344, with 100 illustrations. Philadelphia: P. Blakiston's Son & Co., 1925.

To the first edition have been added sections on defects of the visual fields due to lesions of the temporal lobe; the normal pupillary reactions; intracranial aneurysms and subarachnoid hemorrhage; encephalitis; primary tumors of the optic chiasm; icterohemorrhagic jaundice, and juvenile and adolescent forms of cerebromacular degeneration. The book might well have been called "Ocular Manifestations in Systemic Disease." It deals briefly with changes in the eye which accompany the various diseases. There is an attempt to arrange the material as carefully as possible to conform to anatomic classification, and when this fails, the author has classified the diseases according to nutritional disorders, specific infections, congenital and hereditary conditions, effects of drugs, and parasites. The material presented is largely the author's experience in the wards of St. Bartholomew's and Moorfields. It is well presented, and the book should be of especial interest to medical students for reference, and to the internist.

Diagnostische und therapeutische Irrtümer und deren Verhütung. Innere Medizin. Herausgegeben von Prof. Dr. J. Schwalbe, Geh. San.-Rat in Berlin. Sechzehntes Heft. Die Krankheiten der Leber mit Einschuss der hepatolienalen Affektionen. Von Professor Dr. H. Eppinger, Assistent an der I. Medizinischen Klinik, und Dozent Dr. P. Walzel, Assistant an der I. Chirurgischen Klinik Eiselsberg in Wien. Paper. Price, 7.20 marks. Pp. 134, with 10 illustrations. Leipsic: Georg Thieme, 1926.

This is another of the useful, brief but practical discussions on the avoidance of common errors in the diagnosis and treatment of disease. The present number deals with diseases of the liver and spleen and, like its predecessor, may be recommended to the physican familiar with the German language.

Insects and Disease of Man. By Carroll Fox, M.D., Surgeon, U. S. Public Health Service. Cloth. Price, $4 net. Pp. 349, with 92 illustrations. Philadelphia: P. Blakiston's Son & Co., 1925.

This is divided into two parts. The first part deals with medical entomology and contains a classification and descriptions of the life histories of the insects concerned with disease transmission, together with chapters on the arachnida and the rodents. The second part describes the insect borne diseases under headings such as epidemiology, recognition of the disease and methods of control. While the chapters on medical entomology are quite complete, those on insect borne diseases could well have been expanded to the benefit of the reader.

Handbuch der sozialen Hygiene und Gesundheitsfursorge. Herausgegeben von A. Gottstein, A. Schlossmann, L. Teleky. Erster Band. Grundlagen und Methoden. Bearbeitet von E. Dietrich, A. Grotjahn, V. Haecker, F. Hueppe, P. Krautwig, R. Martin, F. Prinzing, M. Vogel, W. Weinberg. Paper. Price, 30 goldmarks. Pp. 511, with 37 illustrations. Berlin: Julius Springer, 1925.

This is the first part of a comprehensively planned three-volume treatise on social hygiene along familiar German lines. It deals with the history of social hygiene by the veteran Hueppe, with the methods and technic of statistical inquiry including some discussion of data, and with problems of race and heredity, health education, official organization and the like. In the section on public health organization by Dietrich (pp. 432-438) Poland is given more space than England, and the United States is not mentioned.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

An Elementary Course in Tropical Hygiene. Part I. By Mary G. Blacklock, M.B., B.Sc., D.T.M., Lady Medical Officer, Sierra Leone, West African Medical Service. Preface by Andrew Balfour, C.B., C.M.G., M.D., Director, London School of Hygiene and Tropical Medicine. Paper. Price, 1 shilling net. Pp. 44, with 9 illustrations. London: John Bale, Sons & Danielsson, Ltd., 1926.

A pamphlet telling children in story form the important points of hygiene in warm climates.

Intestinal Tuberculosis. Its Importance, Diagnosis and Treatment: A Study of the Secondary Ulcerative Type. By Lawrason Brown, M.D., Chairman of the Medical Board of the Trudeau Sanatorium, Saranac Lake, New York, and Homer L. Sampson, Roentgenographer of the Trudeau Sanatorium, Saranac Lake, New York. Cloth. Price, $4. Pp. 304, with 112 illustrations. Philadelphia: Lea & Febiger, 1926.

Conservative monograph, with excellent bibliography.

Principles of Pharmacy. By Henry V. Arny, Ph.M., Ph.D., F.C.S., Professor of Chemistry in the College of Pharmacy of Columbia University. Third edition. Cloth. Price, $8 net. Pp. 1078, with 289 illustrations. Philadelphia: W. B. Saunders Company, 1926.

New edition, based on the latest revision of the Pharmacopeia and including all recent discoveries.

Operative Cystoscopy. By E. Canny Ryall, F.R.C.S., Founder of and Senior Surgeon to All Saints' Hospital for Genito-Urinary Diseases, London. Cloth. Price, $25. Pp. 47, with 670 illustrations. St. Louis: C. V. Mosby Company, 1925.

American edition of handsomely illustrated British guide to cystoscopy.

A Handbook for Senior Nurses and Midwives. By J. K. Watson, M.D., Capt., R. A. M. C. Cloth. Price, $4. Pp. 554, with 178 illustrations. New York: Oxford University Press, 1926.

Much too much information for nurses and midwives, and some of it none too good.

Practical Helps in the Study and Treatment of Head Injuries. By Adolph M. Hanson, M.D. Cloth. Brice, $3. Pp. 109, with 91 illustrations. Boston: Richard G. Badger, 1925.

Somewhat commonplace practical handbook.

Simpatectomia Peri-Arterial. Por el Doctor Julio Cesar Rivas Morales y por el Doctor Domingo Luciani. Paper. Pp. 84, with 8 illustrations. Caracas, Venezuela, 1925.

Technical debate on a debatable surgical procedure.

Pygmalion. Or the Doctor of the Future. By R. M. Wilson, M.B., Ch.B. Cloth. Price, $1. Pp. 67. New York: E. P. Dutton & Co., 1926.

Reviewed editorially, February 6, p. 419.

Terapéutica General de la Tuberculosis. Por el Dr. Rodolfo Eiselt, Profesor de la Facultad de Medicina de Carlos IV de Praga. Traducción del Profesor R. J. Slaby, revisada por los doctores Angel Pulido, secretario de la Real Academia de Medicina, y José Chabás, director de la Revista de Higiene y Tuberculosis de Valencia. Paper. Pp. 476. Barcelona, 1926.

Proyectos de Organizacion de la Lucha Antipalúdica. Con aplicación a las condiciones hidrográficas y agricolas de las distintas regiones de España. Por el Dr. C. Maturana Vargas. Trabajo premiado por la Real Academa Nacional de Medicina. Paper. Pp. 105. Madrid, 1925.

Proceedings of the Pathological Society of Philadelphia. Containing the transactions of the Society from January, 1924, to January, 1925. Edited by Morton McCutcheon, M.D., Recorder of the Society. Pp. 102. Philadelphia, 1925.

Universidad de Barcelona Facultad de Medicina: Insituto de Fisiologia (Sostenido por la Diputación Provincial). Trabajos publicados durnate el quinquenio 1920-1925. Barcelona, 1926.

Annual Report of the Commissioner of Correction. For the year ending November 30, 1924. The Commonwealth of Massachusetts. Boston, 1925.

American Drug Manufacturers' Association. Fourteenth Annual Meeting, April, 1925. Pp. 398. New York.

El Problema de la Vejez. Por el Doctor J. J. Vigas. Paper. Pp. 22. Caracas, Venezuela, 1925.

Medicolegal

Liability for Medical and Hospital Services

(Irwin v. McDougal et al. (Mo.), 274 S. W. R. 923)

The Springfield (Mo.) Court of Appeals says that in this action, brought by a married woman to recover damages for personal injuries sustained in an automobile accident, the instructions given to the jury authorized it in assessing damages to include bills for medical attention and hospital services. That was error. The married woman's act of Missouri, which authorizes a married woman to contract as a *femme sole* (unmarried or single woman) and makes her separate earnings her own property, does not change the common-law rule by which the husband is primarily liable for the support of his wife, which includes medical attention and hospital service. Had the plaintiff paid these bills, she could recover them in this action. There was no evidence in this case, however, to show that the plaintiff paid, or incurred personal liability for, the medical and hospital bills made necessary by her injury. In the absence of such showing, the liability for those items rested primarily on her husband, and the right of action to recover therefor was in him and not in the plaintiff.

"Sound Health" Properly Defined

(National Life & Acc. Ins. Co. v. Smith (Ga.), 129 S. E. R. 113)

The Court of Appeals of Georgia, division 2, in affirming a judgment in favor of the beneficiary under a life insurance policy, says that it appeared from the evidence that the jury was authorized to find that the insured was in sound health at the time of the issuance of the policy. The term "sound health," as used in a life insurance policy which provides that there shall be no liability under the policy if the insured is not in sound health at the date of the issuance of the policy, is properly defined in the charge of the court as follows:

> If the insured enjoyed such health and strength as to justify the reasonable belief that she is free from derangement of organic functions, or free from symptoms calculated to cause reasonable apprehension of such derangement, and to ordinary observation and to outward appearance her health is reasonably such that she may with ordinary safety be insured and on ordinary terms, the requirement of good health is satisfied. . . . The term "sound health," or "good health," used in a policy, means that the applicant has no grave impairment or serious disease, and is free from any ailment that seriously affects the general soundness and healthfulness of the system.

Under this definition, "sound health" consists, not alone in the outward appearance of sound health, but also in a reasonable freedom from physical derangement and impairment as defined above.

Apprehensions of Injured Woman Not Compensable

(Nevala v. City of Ironwood (Mich.), 205 N. W. R. 93)

The Supreme Court of Michigan says that the plaintiff brought this action to recover damages on account of having broken her left leg, owing to the alleged improper condition in which the city had negligently left a sidewalk. At the time of the accident she was pregnant. She testified that she suffered fear of a miscarriage, worried over the possibility that the child might be deformed by the injury she received, and the labor of childbirth was prolonged and rendered more difficult by her inability to move the broken leg. There was no miscarriage and no deformity occasioned the child by the injuries to the plaintiff. At the trial the defendant asked for the exclusion of this element of pain and suffering, but the testimony was admitted; and, because it was, the judgment which was rendered for the plaintiff is reversed and a new trial granted. If the pains of childbirth were enhanced in consequence of the injuries, that would constitute a proper subject of compensation. But the plaintiff's apprehension of a miscarriage or of the possibility of the deformity of the child she was carrying at the time of the accident was not a subject for the consideration of the jury in awarding compensation.

Society Proceedings

COMING MEETINGS

AMERICAN MEDICAL ASSOCIATION, Dallas, April 19-23. Dr. Olin West, 535 N. Dearborn Street, Chicago, Secretary.

Alabama, Medical Association of the State of, Mobile, April 27-30. Dr. D. L. Cannon, 519 Dexter Avenue, Montgomery, Assistant Secretary.
American Association for the Study of Allergy, Dallas, April 20. Dr. A. H. Rowe, 242 Moss Avenue, Oakland, Calif., Secretary.
American Association of Genito-Urinary Surgeons, Hot Springs, Va., May 10-12. Dr. H. G. Bugbee, 40 E. 41st Street, New York, Secretary.
American Association of Industrial Physicians and Surgeons, Philadelphia, May 24-26. Dr. F. L. Rector, 22 East Ontario Street, Chicago, Secretary.
American Bronchoscopic Society, Montreal, Canada, May 29. Dr. Henry B. Orton, 671 Broad Street, Newark, N. J., Secretary.
American Child Health Association, Atlantic City, May 17-22. Dr. S. J. Crumbine, 370 7th Ave., New York City, Secretary.

New Hampshire Medical Society, Concord, May 25-26. Dr. D. E. Sullivan, 7 North State Street, Concord, Secretary.
New Mexico Medical Society, Albuquerque, May 19-21. Dr. C. M. Yater, 310 N. Richardson Avenue, Roswell, Secretary.
North Dakota State Medical Association, Minot, May 25-26. Dr. A. J. McCannell, Minot, Secretary.
Ohio State Medical Association, Toledo, May 11-13. Mr. Don K. Martin, 131 E. State Street, Columbus, Executive Secretary.
South Carolina Medical Association, Sumter, April 6-8. Dr. E. A. Hines, Seneca, Secretary.
South Dakota State Medical Association, Aberdeen, May 19-20. Dr. John F. D. Cook, Langford, Secretary.
Tennessee State Medical Association, Memphis, May 11-13. Dr. J. F. Gallagher, Jackson Building, Nashville, Secretary.
Texas, State Medical Association of, Houston, May 24-27. Dr. Holman Taylor, 207½ West 11th Street, Fort Worth, Secretary.
Utah State Medical Association, Salt Lake City, May 6-8. Dr. F. B. Steele, Boston Building, Salt Lake City, Secretary.
West Virginia State Medical Association, Morgantown, May 25-27. Mr. S. O. Neale, 211 Smallridge Building, Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1924. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

Annals of Surgery, Philadelphia

73: 1-160 (Jan.) 1926

Diverticula of Esophagus. C. Jackson and T. A. Shallow, Philadelphia.—p. 1.

Odontoid Ossicle of Second Cervical Vertebra. T. W. Todd and J. D'Errico, Cleveland.—p. 20.

*Danger in Use of Lipiodol in Diagnosis of Obstructive Lesions of Spinal Canal. W. Sharpe and C. A. Peterson, New York.—p. 32.

*Radical Breast Operation with Endotherm Knife (Acusector) and Without Ligatures. H. A. Kelly and G. E. Ward, Baltimore.—p. 42.

*Treatment of Gallstones. K. H. Digby, Hong Kong, China.—p. 47.

*Rupture of Intrahepatic Bile Duct with Fatal Peritonitis. W. Smith, Ladysmith, Wis.—p. 55.

Mechanism of Intestinal Perforation Due to Distention. F. T. van Beuren, Jr., New York.—p. 69.

*Iliohypogastric Nerve in Relation to Herniotomy. E. Andrews, Chicago.—p. 79.

*Multiple Sacs in Inguinal Hernia. A. McQueeney, Bridgeport, Conn.—p. 81.

Dislocation of Shoulder. J. H. Stevens, Boston.—p. 84.

Arthrodesis of Elbow. A. P. C. Ashurst, Philadelphia.—p. 104.

Repair of Wounds of Flexor Tendons of Hand. J. H. Garlock, New York.—p. 111.

*Skin Flap Cover for Projecting Intestine. M. E. Steinberg, Portland, Ore.—p. 123.

Perineal Elevator. C. Y. Bidgood, Hartford, Conn.—p. 126.

*Stitch Interpolation in Arterial and Venous Anastomosis. C. Deedera, New York.—p. 131.

Danger of Lipiodol Injections into Spinal Canal.—One cc. of the iodized oil preparation of lipiodol, as manufactured by L. Lafay, Paris, and considered nonirritating to spinal structures, was injected by Sharpe and Peterson by lumbar or cisterna magna puncture into the spinal theca of three patients. The results were of definite diagnostic value in all three cases, but in one case such an inflammatory reaction occurred to the arrested lipiodol at the site of the spinal block in the middorsal area that the patient's symptoms and signs were aggravated to a degree necessitating its removal at a later operation of laminectomy, at which were disclosed two encysted globules of lipiodol surrounded by numerous newly formed adhesions. Roentgenograms of all three patients revealed the unabsorbed lipiodol in the spinal canal, even after an interval of fifteen months following the injection.

Advantages of Acusector.—The advantages accruing from the use of the acusector, according to Kelly and Ward, are: lymphatics, capillaries and small blood vessels are sealed, limiting the number of clamps applied; few or no ligatures are used. Primary union is the rule; the actual depth of tissue destruction on each side of the acusector is 0.1 mm. It is suggested that primary union is promoted because of sterilization of the skin edges.

Treatment for Gallstones.—Digby advocates the following principles in the treatment of cholelithiasis: Operation should be undertaken as soon as a reasonably probable diagnosis of gallstones has been reached. Very free exposure of the biliary tract is desirable, preferably by an angled incision, such as Perthes'. The bile duct should be opened just above the duodenum as a routine measure and the main ducts explored thoroughly from within as well as from without. The removal of the gallbladder and cystic duct should generally though not invariably be practiced, the use of a metal T tube protecting the main ducts from risk of injury.

Rupture of Intrahepatic Bile Duct.—Smith reports an instance of spontaneous perforation of an intrahepatic bile duct, following complete obstruction of the common duct. When perforation occurred, the general peritoneal cavity was flooded with infected bile, and a fulminating peritonitis resulted.

Iliohypogastric Nerve in Relation to Herniotomy.—Andrews interprets the results of his experiments by assuming that the iliohypogastric nerve is motor to the lower fibers of the internal oblique muscle, but that all the motor fibers are given off before the nerve enters the field of operation for hernia, and that, therefore, accidental section of this nerve will not cause any paralysis of this muscle.

Multiple Sacs in Inguinal Hernia.—McQueeney believes that careful examination of cases of inguinal hernia will reveal a large percentage with two sacs—an indirect thin walled sac and a direct fatty sac. During the last four years, nine cases, approximately 7 per cent, with multiple sacs have been noted in a total of 129 cases of various kinds of hernia. Multiple sacs were usually found in fat persons between the ages of 35 and 50.

Skin Flap Cover for Projecting Intestine.—Steinberg describes a method to bring the hollow viscera outside of the abdomen in such a manner as to cause a permanent protrusion beyond the plane of the abdominal wall. The peritoneal lining of the viscus is surrounded with pedicled flaps of skin taken from the abdominal wall. It is suggested that the method might be valuable in performing a colostomy.

Stitch Interpolation in Blood Vessel Anastomosis.—The rule given by Deedera as applicable to venous suture is as follows: The depth of the stitch behind the free margin *should be equal to the distance between the stitches.* This means that when the suture is drawn to close the line of repair, the tissue between opposite stitch holes is double the amount of tissue between adjacent stitch holes. The slight increase in mass of tissues in apposition is sufficient to exert pressure laterally and thus counteract the tendency to constriction of the lumen.

*Id. II. Effect of Pneumococcus Extract on Blood Platelets and Corpuscles. H. A. Reimann and L. A. Julianelle, New York.—p. 97.

Serologic Relationships of Type Specific and Degraded Pneumococci. H. A. Reimann, New York.—p. 107.

*Thymectomy in Rabbit. C. M. Van Allen, New York.—p. 119.

Surface Composition of Normal and Sensitized Mammalian Blood Cells. S. Mudd and E. B. H. Mudd, Philadelphia.—p. 127.

Specific Elements of Tuberculin.—A nonprotein gum has been isolated by Mueller from broth filtrates of human tubercle bacilli grown on a simple medium. It fixes complement and precipitates in high dilution in the presence of homologous immune serum, but fails to give a skin test in tuberculous animals. The preparation and some of the chemical properties of the substance are described.

Streptococci in Acute Rheumatic Fever.—Thirteen strains of hemolytic streptococci isolated by Andrewes, Derick and Swift from patients with acute rheumatic fever did not show any evidence of being related serologically.

Renal Vasoconstriction Causes Albuminuria.—Experiments are described by Starr which show that agents causing renal vasoconstriction also cause transient albuminuria in anesthetized eviscerated dogs. Evidence was obtained that ephedrine is not intrinsically injurious to the kidney. The observed facts may be explained by the conception that renal vasoconstriction causes increase in the duration and extent of the normal intermittent interruptions in the glomerular circulation. Permeability of the glomerular membranes is so increased by these lengthened interruptions that when blood flow is reestablished, albumin escapes. It is believed that this conception may apply to those albuminurias in man which result from excessive muscular exercise or emotion or which are produced reflexly. It may explain the occurrence of albumin in the urine of normal people and in healthy laboratory animals; it may play a part in the explanation of the albuminuria which occurs after anesthesia or in cardiac decompensation. Its possible relation to orthostatic albuminuria is discussed.

Inactivation of Bacteriophage.—Bronfenbrenner and Korb found that addition of neutral salts to the lytic filtrate results in an increased rate of inactivation of the latter when alcohol is added to it. This effect of salts is the more marked the higher the valency of the cation. Conversely, removal by dialysis of salts originally present in the lytic filtrate tends to render the lytic agent less sensitive to alcohol. It appears that inactivation of the lytic agent by alcohol depends directly on the rate of precipitation of the coagulable constituents of the medium, and is not the result of a direct toxic action of alcohol on "bacteriophagum intestinale." These results speak in favor of the chemical nature of the agent of transmissible lysis.

Pneumococcus Extracts Produce Purpura.—Pneumococcus extracts have been shown by Julianelle and Reimann to be capable of producing hemorrhagic purpura in white mice, rabbits, and guinea-pigs. The purpura producing principle resists heating to 100 C. for ten minutes: it resists oxidation; it is filter passing; its activity is destroyed by digestion with trypsin; it is obtained from pneumococcus extracts by full saturation with ammonium sulphate after the acetic acid precipitable substances have been removed from the extracts. The purpura producing principle is common to all four types of pneumococcus and apparently bears no relation to virulence. This principle is not associated with the hemotoxin of pneumococcus, since the hemolytic activity of an extract may be destroyed without effect on the ability to cause purpura.

Effect of Pneumococcus Extract on Blood Cells.—A study has been made by Reimann and Julianelle on the variation in number of the blood platelets, and the erythrocytes and leukocytes of white mice injected with pneumococcus extract. The blood platelets were greatly diminished after the injection, the greatest decrease usually occurring after twenty-four hours. Purpuric lesions usually developed when the number of blood platelets became less than 500,000 per cubic millimeter. Regeneration of the platelets was accomplished by the fourth to the ninth day but there was an overregeneration and the return to normal did not take place until two weeks had elapsed. The erythrocytes were also greatly reduced in number but the rate of their destruction and regeneration was somewhat slower than that of the platelets. The leukocytes were slightly, if at all, influenced by the pneumococcus extract. Pneumococcus extracts were shown to be thrombolytic and hemolytic. Heat destroyed the activity of both the lysins in vitro. Heated extract produced purpura in mice but did not cause a severe anemia. Extracts adsorbed with either blood platelets or erythrocytes showed a marked diminution in their thrombolytic and hemolytic activity in vitro. Such extracts, however, produced purpura as well as severe anemia and thrombopenia in mice.

Thymectomy in Rabbit.—The object of Van Allen's investigation was to determine whether the thymus could be removed completely from rabbits of certain ages without producing any serious disturbance of health which would interfere with their use in other experiments or complicate the interpretation of results. It was found that this could be done.

Cerebrospinal Fluid Sugar Content.—Stowe places the sugar content of normal cerebrospinal fluid in the neighborhood of 75 mg. per hundred cubic centimeters. In cases of neurosyphilis, lethargic encephalitis and other neurologic and nonneurologic conditions, other than the meningitides, the deviation from the normal range and median point is so slight as to be without diagnostic significance. Tuberculous meningitis gives values so definitely above the purulent meningitis cases and so definitely below all other conditions that an almost certain diagnosis can be made quickly in this disease. The occasional purulent fluids obtained after intraspinous therapy, in brain tumor cases with necrosis or hemorrhage near the ventricles and in sympathetic aseptic meningitis, can be delimited rapidly by their normal sugar content from infective meningitis in which the causative organism may not be found promptly. The presence of pus cells alone in the cerebrospinal fluid does not reduce its sugar content. Two of Stowe's cases are interesting in that obstruction to the flow of cerebrospinal fluid at the base of the brain in the one and at the lower dorsal spinal level in the other did not produce any essential difference in the sugar content above and below the lesion. This would suggest that the diffusion of sugar into the cerebrospinal fluid occurs throughout the cerebrospinal axis rather uniformly and not through the choroid plexus alone.

Pharmacology of Benzyl Alcohol.—Gruber's results with the water soluble benzyl derivatives, sodium benzyl succinate and sodium dibenzyl phosphate, confirm former views that the benzyl esters are extremely unreliable for reducing blood pressure. More than 67 per cent of the injections of the former and 35 per cent of the injections of the latter resulted in increased blood pressure. Benzyl alcohol, benzoate and acetate produced rises in blood pressure in 8 per cent of the injections. If a sufficient dose is given to produce a fall in blood pressure, the first effect on the cardiovascular system appears to be slowing the rate and dilatation of the heart with weakened contraction. The respiratory center is always first to be affected, in all injections. Usually there is acceleration in rate preceding the paralysis. It succumbs readily to comparatively small doses and is affected long before the heart is involved. The heart frequently beats some minutes after cessation of respiration. Occasionally an asphyxial rise in blood pressure is noted after cessation of respiration, showing that the vasomotor center has not been paralyzed simultaneously with the respiratory center. Sodium dibenzyl phosphate was found to be more toxic and consequently more depressant to all tissues tested than was sodium benzyl succinate.

Glycolysis at Varying Blood Sugar Levels.—This report by Lemann and Liles indicates that glycolysis proceeds at a lessened rate when the level of blood sugar is raised, not only by glucose (or other food) ingestion, but also by intravenous glucose infusion. The characteristic behavior of glycolysis in diabetic blood specimens may be related to the quantitative level of the blood sugar rather than to any essential quality of the blood. Administration of insulin does not affect the characteristic behavior of glycolysis either in diabetic or in nondiabetic blood. No important rôle is to be attributed to oxalate in evaluating the inhibition of glycolysis.

Substitute for Giemsa Stain.—The substitute for Giemsa stain submitted by French has the following composition: eosin, 1.25 Gm.; methylene blue, 1.25 Gm.; methylene azure A (MacNeal), 0.75 Gm.; methylene violet (Bernthsen), 0.25 Gm.;

methyl alcohol, absolute, 375.0 cc.; glycerin (anhydrous), 125.0 cc. The proportion of the components is the same as that used by MacNeal in the tetrachrome stain, though the concentration is much greater to allow of the customary Giemsa technic. These proportions are said to give the correct blue elements for a complete differential staining of the basic components.

Basal Metabolism Studies.—Values of the DuBois formula for human surface area are tabulated by Stoner by unit centimeter and kilogram intervals for individuals of from 110 to 200 cm. in height and of from 20 to 100 Kg. in weight.

Stability of Standard Kahn Antigen.—Kendrick and Jenks recommend their zinc method for use whenever it is necessary to make a check on the results by the direct method. It is much cheaper and a little quicker than the silver lactate method.

Methylene Azur Stain for Nerve Cells.—Proescher and Arkush have found that methylene azur (thiazin red) and toluidin blue are the only stains of value. They recommend methylene azur, which can be easily prepared in any desired quantity from methylene blue by oxidation with sodium peroxide. The crude methylene azur should be recrystallized, at least three times, from redistilled alcohol. The dyes are dissolved in alkalized chemically pure ethyl or methyl alcohol. They have adjusted the alcoholic solution to ion concentrations varying from p_H values of 7.4 to 12.

Escape from Sympathetic Ophthalmia. L. L. Steele.—p. 187.
Torsion of Fallopian Tube. J. C. Gillies.—p. 187.

Surgical Treatment of Angina Pectoris.—Danielopolu does not agree with Mackenzie that anginal patients should never be treated surgically. The Jonnesco method involving the removal of the stellate ganglion may, perhaps, be abandoned, but the method Danielopolu suggests is said to be far more hopeful, and offers much promise in practice. It consists of intercepting the maximum number of the sensory cardio-aortic fibers without interference with the important groups of the cardiac accelerators. Jonnesco's operation, in which the stellate ganglion is removed, does not fulfill these conditions.

Estimating Size of Prostate.—Fenwick measures the width, length and thickness of the prostrate in a very simple manner by means of probes and then constructs a model with dental wax.

Treatment of Threatened Gangrene.—In two cases cited McEwan made very free incisions in the deep fascia over the whole area of tension. The results are taken to mean that relief of tension was the essential point in treatment. The absence of interference with the actual lesion of the artery, leaving the collateral circulation as intact as possible, contributed to the successful result.

Congenital Clubhand.—A case of defect of the ulna, associated with syndactylism and partial ectrodactylism is reported by Jones and Roberts. The arm was normal as far as the elbow but beyond this the forearm was markedly shortened and bowed outward—while the hand was represented by two fingers fused together, but with separate nails, the smaller one being on the outer side. The other hand and the feet were normal.

Experimental Endocarditis.—Endocarditis has been produced by Wright by injection of pneumococci into immunized rabbits and by repeated injections of nonhemolytic streptococci into rabbits. The lesion so produced has the features of an acute process. There is evidence of marked antibody production by such animals which at the same time show a progressively increasing septicemia such as is found in subacute infective endocarditis in man. The precise conditions for the production of this condition have not been determined.

Sacrococcygeal Chordoma.—Stewart and Morin report the third case of chordoma occurring in Leeds, review the recent literature of the subject and give an account of the fundamental and more or less constant symptomatology of sacrococcygeal chordoma from which, as in the present instance, it is often possible to make a reasonable probable diagnosis even before biopsy. They also describe a recent typical example of chordal heterotopia (ecchordosis physaliphora spheno-occipitalis).

Calcification in Basal Ganglions of Brain.—The so-called "calcification" of the arteries in the anterior half of the globus pallidus is an extremely common occurrence and is found in many diseases affecting various parts of the central nervous system. It was present in fifty of 100 brains examined by Hurst and at all age periods between 20 and 81. The deposit may occur chiefly in the media or it may primarily affect the adventitia and spread to the media later; in cases of atherosclerosis it may also occur in the intima. Often deposits are seen at the peripheral margin of the Virchow-Robin space. The process consists in the infiltration of one or more coats of the vessel with iron salts, the application of suitable tests failing to show the presence of calcium. In the majority of these cases, and in others not showing vascular deposits, degeneration bodies, frequently infiltrated with iron salts, are found in the lenticular nucleus and especially in the globus pallidus. They were present in the globus pallidus in 68 per cent of the cases; in the putamen in 30 per cent. The presence of these vascular deposits and of degeneration bodies is an expression of the proclivity of the affected regions to undergo degeneration in the second half of life, even when not directly affected by the disease to which the patient succumbs. The deposition of iron salts is to be correlated with the high iron content of these parts of the brain.

Effect of Fatigue on Infection.—Fatigue had no influence on the mortality of rats after Boycott and Price-Jones had inoculated them with Gaertner's bacillus. After feeding, Gaertner's bacillus finds its way into the spleens of both fatigued and normal rats, but fatigue much increases the illness and mortality. Repeated fatigue did not break down the natural resistance of the rat to tuberculosis.

Nature of Movements of Omentum.—Experiments made by Florey, Walker and Carleton show that the omentum is totally incapable of any intrinsic movements. The agents whereby the omentum is passively moved about in the abdominal cavity are posture, peristalsis and diaphragmatic movements. Its powers of adhesion and encapsulation are intrinsic.

Effect of Mesenteric Lymph Gland Extract on Leukocytes.—The saline extract prepared by Mole from the mesenteric lymph glands of a spleenless rabbit seems to have a specific effect in producing an increased leukocyte count in the spleenless rabbit. It has not this effect on the normal rabbit whose leukocytes tend rather to decrease after the injection.

Lancet, London

1: 215-268 (Jan. 30) 1926

Syringomyelia of Thirty Years' Duration. W. S. Medley.—p. 229.

Effect of Pasteurization on Tuberculous Milk.—Experiments have been carried out by White with naturally infected milk from cows with tuberculous udders, with milk contaminated with cultures of tubercle bacilli, and with milk to which ground-up caseous tuberculous glands have been added. The method employed was to raise the temperature of the milk to 62.5 C. and to keep it at this temperature for thirty minutes. The results obtained by inoculating such pasteurized milk into guinea-pigs have shown clearly that pasteurization carried out under these conditions ensures a noninfective milk so far as *B. tuberculosis* is concerned.

Pernicious Anemia of Aplastic Type.—In the case reported by Whitby and Jackson the clinical findings and blood picture were similar to those found in the aplastic type of pernicious anemia occurring among munition workers during the late war. It is a significant fact that the patient was by trade a "film varnisher"—an occupation involving the continuous use of some form of "dope"—but the authors were unable to trace any previous cases of disease among such workers or to find any evidence for the occupation being the primary cause of the disease.

Action of Antimony Tartrate Injections.—Patients subjected to a prolonged course of intravenous injections of antimony frequently exhibit signs of hypersensitivity—presumably an example of drug allergy—with nontoxic doses. It is suggested by Christopherson and Gloyne that the signs of this hypersensitivity may be due to an alteration of protein metabolism and in extreme cases may resemble true protein shock. The viscera of a man who had died from accidental error of dose of intravenous antimony showed degeneration and destruction of the parenchyma of liver and kidneys. Four rabbits succumbed to intravenous injections of antimony tartrate in doses ranging from ⅛ grain to ½ grain. The postmortem changes noted in these animals were: (*a*) dilation of blood capillaries, (*b*) effusions into serous membranes (pericardium and peritoneum), (*c*) hemorrhages into lungs and spleen, and (*d*) retention of urine. The chief histologic lesion noted in these animals was degeneration of the hepatic cells. Similar, but less constant and less marked, degenerative changes were found in the kidney tubules. An attempt was made to protect a rabbit against the toxic effects of antimony by injecting sodium thiosulphate shortly after each dose of the antimony. The animal died after receiving 4½ grains of antimony over a period of twenty-three days. One rabbit of the preceding series, died after receiving 4⅛ grains in sixteen days without attempted protection with sodium thiosulphate.

*Vaccination Against Tetanus. C. Zoeller and G. Ramon.—p. 104.
Three Species of "Penicillium." A. and R. Sartory.—p. 114.

Anatoxin for Vaccination Against Tetanus.—Zoeller and Ramon's research was made on 100 subjects. After one subcutaneous injection of 0.5 or 1 cc. of anatoxin, the serum from the vaccinated subjects, a month later, did not immunize guinea-pigs against one lethal dose of toxin. A month after an injection of 2 cc. of anatoxin, given fifteen days later, the serum neutralized from one to ten lethal doses of toxin. Repeated injection evidently enhanced the acquired reactivity. Serum from subjects given three injections of anatoxin neutralized from 500 to 3,000 lethal doses of tetanus toxin, after eight days. In seven persons, anatoxin was injected simultaneously with 5 cc. of tetanus antiserum; the amount of antitoxin as well as the acquired reactivity appeared unchanged. Under associated injections of anatoxin and antityphoid vaccine, the acquired reactivity was enhanced, and agglutination of typhoid bacilli occurred as usual. An active immunity was thus induced simultaneously against typhoid and tetanus. Antiserum treatment still remains the method of choice in emergency cases, since the development of active immunity is slow. The antiserum and anatoxin can be advantageously combined: the first to avert immediate manifestations of the tetanus; the second, tardy occurrence. The injections of anatoxin were not accompanied by any untoward by-effects.

An Epidemic of a Special Form of Encephalitis.—David and Dekester describe an epidemic observed last November in a suburb of Lille. Their statistics include six children, twenty-five women and nineteen men. Five or six members of the family became ill at once, but no cases of contagion were noted in the environment. After a short incubation, the disease started with swelling of the face and eyelids, conjunctivitis and high fever. Then pain appeared in the legs, soon followed by paraplegia with abolition of the reflexes, but without disturbances of the sphincters. This was accompanied by contraction of the muscles of the spine, nuchal rigidity and Kernig's sign. The whole body became almost as stiff as a board. The oculomotor centers seemed to be intact, while there was involvement of the bulbar centers, especially of the glossopharyngeal and vagus nerves. The sensory and mental condition appeared normal. Arterial hypotension was associated with hypotension of the cerebrospinal fluid. Edema of the legs was sometimes manifest late in the disease, but there was no albumin in the urine. The morbid phenomena disappeared in from eight to fifteen days in mild cases; in grave cases death usually occurred within a few weeks. Cultures of the blood and cerebrospinal fluid were negative; the affection may have been induced by a neurotropic virus, possibly analogous to that in encephalitis. The special features of this encephalitis may be explained by localization of the virus in the spinal cord and medulla oblongata instead of in the mesencephalon. Cases of low encephalitis, of polyneuritic type, have been reported before (Beriel and Devic).

Hypertension-Inducing Action of Salt.—Ambard and Cahn report the case of a man with hypertension who developed acute edema of the lungs, for which salt in the food appeared to be responsible. The hypertension was accompanied by albuminuria, uremia and dry chloride retention; there was no dropsy. On a salt-free diet the arterial tension declined, but it increased rapidly by 4 cm. of mercury when the restriction of salt was suspended. Evidently the rise in the blood pressure did not depend on the edema, but probably on the concentration of chlorine in the tissues.

Variations of the Alkali Reserve.—Ambard, Schmid and Adnot's conclusions are based on five observations. A manifest connection seems to exist between the content of sodium chloride in the food and the alkali reserve. The latter increases under restriction of salt, and decreases with its intake. The phenomenon is manifest in healthy persons; still more in those with different kidney diseases. No correlation seems to exist between the alkali reserve and the chlorine of the plasma. It is possible that an excessive concentration of chlorine in the respiration centers modifies the ventilation of the lungs, indirectly reducing the alkali reserve. Thus may be explained why there is no close relation between the uremia and the alkali reserve in nephritis, since there is no close relation between uremia and chlorine retention.

Parkinsonian Tremor on One Side, Arthritis on the Other.—May reports two cases of a parkinsonian syndrome in men, aged 60. The tremor was limited to the left arm, with acute arthritis of the right hand with contracture. Both affections appeared simultaneously, soon after herpes zoster. This seems to demonstrate that an infection of the nervous system may be the common origin of both. The presence of diplopia in one case, and of attacks of somnolency in the other suggest that a masked epidemic encephalitis may have been the causal factor. Tentative treatment as for syphilis proved futile. The condition has persisted for eighteen months to date in one case; a delusion of persecution developed the fourth month in the other patient, compelling institutional restraint.

Tonus of the Vegetative System in Hyperthyrosis.—Krause studied the vagosympathetic tonus of 100 patients. He gives here the results in two with exophthalmic goiter, two with hyperthyroidism and five with pulmonary tuberculosis of pseudothyroid type. Exaggerated tonus of the sympathetic and vagus was noted only in one; predominantly of the sympathetic in eight, while the tonus of the vagus remained normal or even decreased.

Rise of Arterial Tension from Sodium Citrate.—Renaud relates that large doses of sodium citrate, from 8 to 12 Gm., were given to twelve patients with arteriosclerosis. This induced gradual increase of both the systolic and diastolic arterial tension. No functional disturbances of any kind were observed. As soon as the intake of the citrate was suspended, the tension became normal within two or three days. Sodium citrate may exert a direct action on the center controlling the tension. The blood pressure should be carefully examined in cases of prolonged administration of the drug.

Action of Certain Substances on Contraction of the Gallbladder.—In some of the cases described, the use of the duodenal tube and injection of magnesium sulphate had been preceded by subcutaneous injection of pilocarpine. The drug appeared to enhance the stimulating action of the magnesium sulphate on the secretion of bile. Chiray, Lebon and Callegari's further experiments confirmed that pituitary extract induces contraction of the gallbladder. The contraction was rapid, durable and strong, even in the cases in which direct stimulation of the gallbladder had been of no avail. Probably, the influence of the drugs on gallbladder contraction is due to their action on the vagus. Thus the use of these drugs may be indicated in stasis of the gallbladder from atony, a condition which is at least as frequent as mechanical stasis from pericholecystitis, stenosis or gallstones. It is thus possible by general medication to induce a kind of physical training of the gallbladder. Two patients treated on this basis were materially improved, overcoming the stasis of the gallbladder. The pituitary extract test may reveal the real condition of the gallbladder, and therefore indicate whether a cholecystectomy is necessary or not.

Visualization of the Duodenum and Gallbladder by Oral Technic.—Chiray gives the phenoltetraiodophthalein in pills, and states that in sixteen of his twenty-one cases the roentgenograms were as distinct as when it was given by the vein.

*Significance of Eosinophilia. Schmite.—p. 227.
Grave Rectocolitis. E. Antoine. Supplement.—p. 1-48.

Diagnostic Value of Eosinophilia.—Schmite specifies three groups of diseases in which an excess of eosinophils in the blood may aid in diagnosis. In diseases of parasitic origin, especially hydatid cyst and chronic amebiasis, the clinical signs may remain uncertain and the parasite escape detection; eosinophilia may be the only element to suggest the diagnosis. Marked eosinophilia with digestive disturbances may reveal the presence of intestinal worms. It is most pronounced with the hookworm, and is inconstant in leishmaniasis and trypanosomiasis. An increased number of eosinophils is observed in certain blood diseases, especially leukemias. It is important in the myeloid form and is rare in the lymphoid.

In the febrile stage of Hodgkin's disease, an excess of eosinophils in the blood coexists with that in the tissues. Eosinophilia is frequent in skin diseases of erythema or pemphigus type; it is constant in herpetiform dermatitis. A fourth group is represented by cases of intense eosinophilia in which the number of eosinophils surpasses 65 per cent, and the number of leukocytes is normal or increased. The pathogenesis of this eosinophilia is still unknown. Reappearance of eosinophils in the blood indicates a tendency to recovery. According to Markowich and Gueratovitch, eosinophilia is excessive in the mild form of scarlet fever, absent in the grave form. Disappearance of eosinophils in amebiasis and hydatid cyst testifies to a complicating abscess. Differentiation of essential asthma from pseudo-asthma, in heart or kidney disease, may be based on the absence of eosinophilia in the latter. Eosinophilia does not accompany all anaphylactic conditions; it is inconstant in migraine and exceptional in urticaria.

*Diarrhea in Breast-Fed Infants. L. Bytsch.—p. 40.
Vaccine Dressings for Pyodermatitis in Infants. E. Odier and S. Dreyfus.—p. 44.

Ultraviolet Rays in Treatment of Fissured Nipples.—Chatin applied ultraviolet rays in twelve cases of cracked or fissured nipples. The treatment was given on alternate days. The first exposure was for two minutes, gradually increasing by two minutes up to ten. Pain was sometimes relieved by the first exposure; healing was rapid, and a complete cure occurred within one or two weeks.

Treatment of Primary Diarrhea in Breast-Fed Infants.—Bytsch refers to cases of diarrhea in breast-fed infants, occurring in the first days of life. According to Marfan, the diarrhea may be due to hypersensitization of the intestine to the maternal milk. The affection is not grave, never inducing marasmus. The treatment consisted in the following: Toasted slices of wheat bread were ground and sifted. Two teaspoonfuls of this powder were boiled in 100 Gm. of weak tea, and sweetened with a little sugar or saccharin. Two teaspoonfuls of this gruel were given before each feeding, four or five times a day. Improvement was noted in two or three days. By the second to the fourth day there were no more than three or four stools daily. The infants regained appetite and gained in weight. This method of feeding was sometimes continued until the infant was 3 months old. The breast feeding had never been interrupted.

*Case of Periarterial Sympathectomy. J. M. Vilardell.—p. 162.
Discussion on Rheumatism at British Conference. R. Clément.—p. 162.

Cholesterol and Uric Acid in Gout Under Thorium Treatment.—Cluzet, Piéry, Chevallier and Dubost treated successfully a patient with a grave form of articular gout and anemia by inhalations of thorium emanations. Two roentgenograms are given showing the favorable changes in the joints. While the daily elimination of uric acid before the treatment was 0.5 or 0.6 Gm., under the first month of treatment with thorium it reached 1.75 Gm. With a daily intake of 4 liters of fluids, the parallel course of the diuresis and uric acid elimination was evident. Reduction of the liquid intake by 2.5 liters was followed by a severe attack and increase of uric acid in the blood. The content of cholesterol per liter of blood rose from 0.5 to 2 Gm. after the thorium inhalations. The concentration of cholesterol in the blood may be due to the stimulating action of the thorium on tissue activity.

Periarterial Sympathectomy.—Vilardell reports recovery after periarterial sympathectomy in a case of accidental severing of the ulnar nerve. Suture of the nerve had not checked the gangrenous process, with sloughing off of the little finger in two weeks. The ulcer of the stump did not yield to electrotherapy or other methods used for eight months. Removal of the adventitia of the middle third of the brachial artery induced complete healing in twenty-one days. The cure has persisted for two and a half years to date.

Glucose in Treatment of Gonorrhea. G. Ichok.—p. 181.
Galen's Organotherapy in Psychiatry. R. Van der Elst.—p. 187.

Pathogenesis of Biliary Colic.—Chiray and Pavel assert that a migrating gallstone, foreign body or inflammation of the gallbladder does not induce a biliary colic; they only favor its appearance. Spasmodic contraction of the gallbladder, from excessive stimulation of the vegetative system, is the determining factor of the colic. Among the arguments to sustain this conception of the cause of the paroxysm of pain are the sudden occurrence and disappearance of certain colics under the mere influence of an emotion as, for instance, grief, in the absence of a gallstone or foreign body. Then, the short duration of certain paroxysms, persisting less than an hour, sometimes only a few minutes. An important argument, they say, is also the experimental contraction of the gallbladder with a subsequent painful paroxysm, from injection of magnesium sulphate into the duodenum.

Resuscitation of the New-Born by Intracardiac Injection of Epinephrine.—After the usual attempts to restore respiration had failed, Garipuy and Mériel injected into the heart 1 cc. of 1:1,000 solution of epinephrine in a newly born infant with white asphyxia. Heart beats reappeared as soon as the injection was finished. Artificial respiration and traction of the tongue were continued for fifteen minutes longer, when normal respiration was established permanently. They emphasize that the intracardiac injection should be used by obstetricians as a routine procedure at need, since the method is easy, rapid and highly effectual.

Cancer Statistics. A. Renaud.—p. 106. C'td.
*The Blood After Roentgen Rays and Tuberculosis. A. Epstein.—p. 111.

The Principles of Therapy.—Hausmann would like to see less use of statistical methods and of fatalistic theories as to heredity in the standpoint of the practitioner. They are valuable only for the present and the past aspect of the disease. The mortality from puerperal fever used to be 10-20 per cent, until Semmelweis saw that this was not necessary. One dies inevitably from a certain disease, until the day comes when one does not have to die from it. The actual happenings differ from the possibilities, and because of the complexity of conditions no single law of nature has a fatalistic power. Medical science warns against what Bleuler calls autistic thinking; medical art requires it to a certain extent.

The Blood After Roentgen Rays and Tuberculosis.—Epstein found that irradiation of a guinea-pig with 1,000 R. units suppressed for twenty days the increase in neutrophils, and later also in lymphocytes, which would otherwise follow an intraperitoneal infection with tubercle bacilli. A dose of 100 R. units enhanced it. No difference in the course of the tuberculosis was noted between such animals and those that had not been irradiated.

*Hernia as an Industrial Accident. L. Ribeiro.—p. 311.
*The Verumontanum from the Clinical Standpoint. A. Valerio.—p. 313.
*Avoidable Keratitis. E. Campos.—p. 319.

Hernia and Industrial Accidents.—Recent legislation in Brazil on workmen's compensation has raised the question confronting other countries, namely, when can a hernia be regarded as an industrial accident? The Brazilian law requires for accepting this that the accident must be the sole and single cause of the hernia. But the courts have interpreted the law otherwise. In other countries it is the general opinion that of 1,000 cases of hernia, an industrial accident might be incriminated for it in only two or three instances. Ribeiro's experience with sixty-five cases testifies to the same approximate proportion. It is only exceptionally that a hernia can be ascribed to physical injury as it is almost always of slow development, in persons congenitally predisposed to it. The traumatism does not represent the principal cause but merely aggravates the preexisting lesion of which the bearer may not have been aware. Systematic physical examination of all workmen, as is done in military circles, would solve the problem.

Disease of the Verumontanum.—Valerio found evidences of inflammation in seventeen of twenty-six cases and a cyst, polyp or papilloma in the nine others, explaining the disturbances, which had been variously ascribed to the prostate, seminal vesicles or urethra proper. Every one was permanently cured by local treatment, either application of a caustic or the galvanocautery. Posterior urethroscopy is indispensable in all chronic disturbances in this region.

Avoidable Keratitis.—Campos expatiates on the necessity for protecting the cornea when the eyelids gape during long periods of unconsciousness or long sickness. His text is an infant with ulceration of both corneas, exactly corresponding to the ellipse left by the gaping eyelids during the semicomatose phase of prolonged toxicosis. The keratitis might have been prevented by closing the eyelids with a couple of strips of adhesive during the prostration. Infants are especially liable to need this.

*Cardiac Epilepsy. M. P. Abascal and J. M. Cerviño.—p. 223.
*Prolonged Fever of Syphilitic Origin. E. Figari Legrand.—p. 239.

Cardiac Epilepsy.—Abascal and Cerviño apply this term to designate a tendency to epileptic seizures when the circulation in the brain is hampered from pathologic conditions in the heart. A case is described in which the circulatory disturbances seemed to be the sole cause of the epilepsy. In the last few years the man had been having attacks of severe pain in the lumbar region and back of the neck, ascribed to rheumatism. Later, palpitations and dyspnea on exertion incapacitated him almost completely. When a child, he had been kicked in the precordial region by a horse, and the wall of the chest was deformed, the heart much dilated. There were no motor disturbances, but acute edema of the lungs often followed the unconsciousness of the seizure. Under treatment addressed to the heart, the dyspnea subsided. In a second, similar case, there was congenital absence of the right pectoralis muscle. In both the minor manifestations of epilepsy had preceded the manifest heart disease. In the first patient they first appeared after an attack of typhoid.

Protracted Fever of Probably Syphilitic Origin.—A young woman with no appreciable signs or symptoms of congenital syphilis had persistent fever after an attack of what seemed to be influenza. The fever continued for ten weeks, rebellious to all measures, including shock treatment, organotherapy and heliotherapy. The late date of puberty in the patient and one sister was the only feature of the case suggestive of syphilis, but under tentative mercurial treatment the fever was promptly arrested and the general health showed marked improvement. The parents were first cousins.

Revindication of Humanized Vaccine. M. S. Yglesias.—p. 133.
*Rupture of the Perineal Urethra. N. L. Melo.—p. 142.

Rupture of the Perineal Urethra.—In the first of the two cases described by Melo, the healthy young man had fallen astride an iron bar and the hematoma that formed was evacuated the third hour after the accident. The posterior stump of the bladder could not be located until after injection of methylene blue. The lesions promptly healed after passage of a grooved sound into the bladder, with a retention catheter. In the other case five days had elapsed after the bullet wound before the patient reached the hospital, and infection was already installed, compelling diversion of the urine. Both patients made a smooth recovery and the urethra of the first patient was normally permeable over three years later.

Diverticulum of Bladder Treated Surgically. Maraini and Quintana.—p. 176.
Complete Retention with Large Adenoma in the Prostate. B. Maraini and J. N. Dante.—p. 179.

Harmless Extraction of a Hairpin in the Bladder.—Two days after the hairpin had slipped into the bladder, the last of the urine was slightly blood stained, and micturition was frequent. Pagliere gives an illustration of the device with which he then easily extracted the foreign body. After cutting off the tip of a no. 14 catheter, he passed through it a copper wire, bending the tip to form a round hook. The wire was then drawn back until the hook fitted over the tip of the catheter. It was then passed into the cystoscope and introduced into the bladder.

The Importance for Urology of the Roffo Neutral Red Serologic Test.—Astraldi and Rivarola state that the response was constantly positive in their six cases of cancer of the prostate tested, and in the three cases of cancer of the bladder with histologic confirmation. In three of six cases with cystoscopic findings suggesting cancer of the bladder, but not confirmed otherwise, the response was positive in three and negative in three. It was also constantly negative in four cases of adenoma of the prostate and in two of polycystic kidney. As already mentioned in these columns, Roffo adds to 2 cc. of fresh, centrifugalized serum 5 drops of a 5 per cent solution of neutral red. The yellow tint persists with normal serum, but it veers to red with cancer serum.

Case of Hydatid Cyst of the Kidney. J. A. Etchepareborda.—p. 582.

Tabetic Vomiting Crises.—In the three cases described by Escudero and Tobías, the attacks of vomiting were the only gastric symptoms of the tabes. In one they were preceded sometimes by pains in the spine and lumbar region, and two presented marked asthenia. The clinical manifestations soon confirmed the tabetic origin. Bismuth relieved the attacks of vomiting. In the intervals, the stomach seemed sound, and there were no gastric pains at any time. Tobías has obtained favorable results with radiotherapy in ordinary gastric crises in certain cases.

No Relation Between the Cholesterol and Calcium Content of the Blood in Relation to Thyroid Function or to the Basal Metabolism.—Summarized recently when published elsewhere.

Stomach Function Test.—Bergman gives a test meal of gruel (two tablespoonfuls of oatmeal in 1 liter of water, boiled slowly down to 500 cc.) and immediately afterward injects 5 cc. of a 1 per cent aqueous solution of neutral red into the buttocks. Stomach content is aspirated every fifteen minutes thereafter as long as any is obtainable, continuing the examinations for three hours at least. In his seventy tests of the kind, the neutral red did not pass into the stomach content when the mucosa was gravely diseased.

Cholesterol in Treatment of Anemia.—Escudero and Puchulu relate that a woman with tuberculosis of six years' standing and grave anemia was treated with cholesterol, and gained 11 Kg. and the blood picture returned to practically normal. The leukopenia persisted, testifying to pathologic conditions in the spleen. They state that the erythrocytes had increased from 1,660,000 to 6,000,000 and the hemoglobin from 22 to 80 per cent by the fiftieth injection of 0.2 Gm. of cholesterol, in 5 cc. of olive oil, in ten weeks. The rapid improvement under the cholesterol alone confirmed the favorable reports of others in this line. They review the literature on the action of cholesterol in experimental and clinical experiences.

So-Called Traumatic Neuroses.—Bonhoeffer regrets that the practical consequences have not kept pace with the development of scientific knowledge on the so-called traumatic neuroses. The symptoms following real concussion of the brain resemble Korsakoff's syndrome, or they consist of a more or less pronounced amnesia, or convulsions, or disturbances of tolerance for alcohol and periodic depressive states. They can be easily distinguished from the purely functional troubles. Fright may produce a vasomotor complex, but only for a short period, unless there is the wish to draw advantages from it. Traumatic hysteria is not a disease, but only a psychologic reaction which occurs only with certain wishes and disappears if they are given up. The complaisant or ignorant physician injures not only the state or the insurance company, but also the victim of the trauma, who keeps his symptoms as long as he can hope for compensation. Hospitals for soldiers with traumatic neuroses were required for their own soldiers, never for the millions of prisoners of war who knew that they were out of danger. He agrees with Hauptmann's opinion that no compensation should be allowed in "compensation hysteria." His points out that experience on the causal relation between liability legislation and traumatic hysteria is old, as well as the knowledge that such subjects recover after getting an indemnity. As long ago as 1894, Ricolins spoke of "gold treatment which can be made with bank notes." The diagnosis is quite safe, only injuries of the head require special attention. As long as the law grants an indemnity, a single payment is preferable to doling out the sum, which only prolongs the symptoms. He is against any compensation where the wish factor is predominant. In mixed cases he agrees with the findings of the Swiss conference to the effect that if the symptoms are such that they would not occur in a noninsured person, the claim should be rejected.

Sanocrysin.—Klemperer has treated forty-two patients suffering from pulmonary tuberculosis with sanocrysin for a whole year. He concludes that the antiserum only aggravates the sanocrysin poisoning. Doses of 0.5 and 1 Gm. to begin with are harmful. Doses of 0.1 and 0.25 Gm., slowly increasing to 0.5-1, are not injurious. The treatment is useful in some cases, useless in an equal number of others, but it is impossible to predict which action will occur. A debate on this paper is also reported.

Water Metabolism.—Marx gave the suggestion of drinking to hypnotized subjects. They reacted by polyuria with a low specific gravity of the urine, and dilution of the blood, followed by inspissation. These experiments throw light on the theory of polyuria and polydypsia and their psychic origin.

Avitaminosis and Healing of Fractures.—Israel and Fränkel found that fractures in guinea-pigs do not heal if the animals are kept on a diet free from vitamin C. A mere restriction of the vitamin, which is sufficient to retard the growth of the animal, does not impair the formation of callus. They observed a fracture of the callus in one animal put on the vitamin free diet after the healing had become evident. The incentive to this work was given by Bier who found analogous observations on the reopening of ulcers and fractures in sailors, quoted in Sir Astley Cooper's lectures, which are 100 years old.

Roentgen Rays and Micro-Organisms.—Schneider irradiated yeast with roentgen rays. The yeast lost about 10 per cent of its fermentative activity if irradiated during fermentation and in the presence of electrolytes. Otherwise he confirmed the resistance of unicellular organisms to the roentgen rays. Even photosensitization with eosin made no difference in yeast. He explains the resistance of micro-organisms by their relative independence from the medium, which is the main point of action of the roentgen rays.

Reaction of Infusion Fluid.—Endres confirms the increased acidity of the blood after hemorrhage. In spite of this, an alkaline injection fluid is contraindicated because it would inhibit the dissociation of oxyhemoglobin. The increased acidity promotes this after the hemorrhage in a similar way as in high altitudes. The ideal injection fluid would be slightly acid, he thinks.

Nuclei of Leukocytes in Syphilis.—Lemke and Streblow confirm the presence of changes of the nuclei of leukocytes and lymphocytes described by Antoni in syphilis. In an arrangement excluding completely self-suggestion, they made a correct diagnosis in 90 per cent of the cases. Other diseases —especially anemia—may give pictures which resemble the typical ones, but a coincidence of weak staining of nuclei, irregular outlines, and formation of Antoni's canals is practically pathognomonic of syphilis.

Blood Volume with Splenomegaly.—Greppi found with the congo red method very high figures for the blood volume in three cases of leukemia, and only a little less in three cases of splenomegaly of other origin. He believes that the method is unreliable in such conditions probably because of a rapid absorption of the dye by the spleen.

The Lymphatic Organs. L. Aschoff. Supplement.—pp. 1-22.

Syphilis and Interruption of Pregnancy.—Buschke and Gumpert have collected statistics on the grave outlook for children with congenital syphilis. They recommend consideration of abortion if the life of the mother is in danger, or if regular and intensive treatment of the syphilis during pregnancy is impossible, or if there are cases of neurosyphilis in the family, and if its financial distress is great.

Moral Aspects of Abortion and Birth Control.—Vogtherr analyzes the moral point of view in respect to birth control and interruption of the pregnancy in the first months. He sees only two possible consistent attitudes: the one which condemns morally both birth control and abortion, except in serious danger for the mother; and the other which approves of both methods of "rationalization of human procreation." A physician who refuses indignantly (instead of by simply referring to the law) to perform an abortion, but who does not hesitate to give his advice on how to prevent conception, is not a logical thinker, or else he is a hypocrite.

"An Ovarian Hormone." S. Loewe.—p. 289.
*Epinephrine and Pregnancy Vagotonia. B. Varó.—p. 291.
Serum Proteins After Operations. K. Burger.—p. 294.

Nodes and Cysts on Tubes.—Schiffmann and Steiner conclude that the small nodes and cysts localized on the fallopian tubes are only normal formations, due perhaps to a local peculiarity of the peritoneum.

Colostrum Secretion and Gynecologic Disease.—Ballin does not consider colostrum as a sign of pregnancy up to the fifth month. Women who have been pregnant, and especially those who have nursed for a long period, may have colostrum for years. Ovarian changes, especially cancer, and the menopause may cause secretion of colostrum.

Local Autohemotherapy of Mastitis.—Rubeška prefers to inject 40-60 cc. of the patient's blood into the thigh. The injection has to be made early, and be repeated the next day if the temperature is not normal.

Epinephrine and Pregnancy.—Varó observed no increase of the agglutination titer against typhoid bacilli after injection of epinephrine in nine pregnant women. He confirms the increase observed by Borchardt in normal subjects, but it was absent in nonpregnant vagotonic women.

Mechanism of Immunity in Tuberculosis.—Lubarsky and his co-workers inoculated rats, mice and guinea-pigs with tubercle bacilli. No bacteriolysis or lipolysis was observed in the organism thus immunized against tuberculosis. The immunity seemed to be of a cellular character. Fixation of tubercle bacilli occurs as a process to render them harmless, isolating them in the immunized organism, and thus producing the tubercle. Tubercle bacilli are eliminated by way of the bile and intestine. The mechanism of the immunity realized seemed to be the same with virulent, and slightly virulent bacilli and with acid-resisting saprophytes.

Mental Abilities of Rats.—Sadovnikova-Koltzova's tests were made on 123 rats. No difference was noted between the mental ability of the males and females, but there was a manifest correlation between the mental equipment of the parents and their offspring; and also between animals of the same litter. The teaching of parents did not influence the abilities of the offspring. In the mental ability of the rats a group of three genes seemed to be involved, a gene of general activity, a gene of fear, and one of a seeking instinct.

Peroxidase Function of Oxyhemoglobin.—Bakh and Kultiugin consider oxyhemoglobin a peroxidase ferment. It is a biological catalyzer, produced by the living cell. Its ferment nature cannot be denied on account of its resistance to heat. Bakh obtained a perfect peroxidase from horseradish by ultrafiltration, still active after prolonged heating. The catalyzer property in oxyhemoglobin seemed to resist the action of acids better than in vegetable peroxidase. The data presented demonstrate that there is no evidence against accepting oxyhemoglobin as a peroxidatic enzyme.

Experimental Avitaminosis in Pigeons.—Tcherkes induced symptoms of vitamin B deficiency in pigeons deprived entirely of vitamins. An increased intake of fat did not influence the avitaminosis B on an exclusive fat diet, but the avitaminosis B process became accelerated in the presence of protein and carbohydrates. The lack of vitamin B induced first disturbances of carbohydrate and protein metabolism; then of fat metabolism.

THE TREATMENT OF FUNCTIONAL UTERINE HEMORRHAGE *

EMIL NOVAK, M.D.
BALTIMORE

In the great majority of cases of uterine hemorrhage, the indication for treatment is perfectly clear. A definite anatomic lesion can be demonstrated in one of the pelvic organs, and the removal of such a lesion is the sine qua non for the cure of the abnormal bleeding. For example, the most common of all causes of persistent uterine hemorrhage is incomplete miscarriage, and the spontaneous or operative removal of the retained gestation products is followed by a cessation of the bleeding. In the same way, bleeding due to pelvic neoplasm or to pelvic inflammatory disease necessitates removal of the lesion.

In a much smaller but still not inconsiderable group of cases, however, uterine bleeding may be observed in the entire absence of any demonstrable gross lesions of the pelvic organs. Indeed, extremely profuse hemorrhage may occasionally be observed in children at or near the age of puberty. Far more frequently such bleeding is noted in women at or near the menopausal age, although no period of reproductive life is immune from this possibility. Cases of this type are commonly designated as "functional," "idiopathic" or "essential." The hemorrhages are occasionally mild, and may tend toward spontaneous correction. More frequently, they are sufficiently severe to lead the patient to seek medical advice, and not infrequently they are quite alarming, causing grave concern to both patient and medical attendant. In those cases which occur at or near the climacteric, it can at once be seen why this should be so, for free bleeding at this period brings with it the apprehension of cancer. The diagnostic conflict between climacteric bleeding of functional nature and that due to cancer is thus very frequent, and this fact alone is sufficient to warrant consideration of the less dangerous though less well understood of these two causes of bleeding.

In previous papers,[1] attention has been called to the clinical characteristics of this form of abnormal uterine hemorrhage, and especial stress has been laid on the fact that in by far the largest number of cases, the uterine mucosa yielded by curetting presents a very characteristic picture. This was originally described by Cullen and designated as hyperplasia of the endometrium.[2] I shall not describe the condition in detail here, except to say that it is characterized by a genuine increase in both stromal and epithelial elements, and that perhaps the chief distinguishing feature is a marked disparity of the glands, many of which are large and cystic, while others are quite small. There is thus produced a very characteristic Swiss-cheese pattern, often so marked that a glance through the microscope is sufficient to make the diagnosis. Grossly, the endometrium in some cases is so enormously overgrown that huge quantities are brought away by the curet, and in older women may give rise to a snap diagnosis of malignancy, unless one is accustomed to the naked eye diagnosis of tissue material. Usually, in such cases the mucosa is distinctly polypoid, constituting the condition that has so often in the past been wrongly designated as "polypoid endometritis." Most frequently the endometrial overgrowth is only moderate, and it may be absent altogether.

Certain ovarian lesions have been described as characteristic accompaniments of this endometrial condition, especially an absence of corpora lutea and an increase in the process of follicular maturation and atresia. There is some question as yet as to the invariability of these findings, but they certainly constitute the common ovarian picture in cases of this group. The fact that bleeding of this type occurs only in the reproductive period of the woman's life, that it so commonly recurs after curetting, that it is curable always by removal of the ovaries or by radiotherapy—these and a number of other considerations make it almost certain that the causation is to be sought in an endocrinopathy of some sort. Whether or not this is to be classed as a hypergonadism (hyperoophorism), or just what the real disturbance is, cannot of course as yet be stated.

In a rather large experience with this form of uterine bleeding, from both the clinical and pathologic standpoints, I have been impressed with the fact that the profession as a whole and, indeed, gynecologists as a group, have not yet come to appreciate the real nature and significance of this form of menstrual disturbance, as well as its great importance from the standpoint of differential diagnosis. Too often a diagnosis of "idiopathic" hemorrhage is made without proper measures to exclude the possibility of other and often far more serious lesions, such as cancer. Even when the diagnosis is correct, many practitioners prescribe ergot, stypticin or other drugs of this sort, without any real pharmacodynamic justification. Ergot, for example, is an excellent remedy in cases of uterine hemorrhage due to relaxation or insufficiency of the uterine musculature. It probably has no hemostatic virtue in other forms of hemorrhage, such as those due to a biochemi-

cal or endocrine disturbance. This is not to say that any brilliantly effective medication can be suggested in the group of cases I am describing. My object is rather to outline what I take to be an intelligent plan of management. Unfortunately, it will be seen that from the standpoint of mere medication, the measures recommended below often give results no less disappointing than those obtained from the drugs criticized above, although the rationale of their employment would seem reasonably clear.

METHODS OF TREATMENT

Spontaneous Cure of Mild Cases.—Any one who has taken a large number of menstrual histories will recall the occasional statement that the menstrual periods were very profuse and perhaps irregular for the first year or two after inauguration of the function, but that later the trouble had apparently adjusted itself and the periods had become regular in occurrence and normal in amount. In the same way, it is probable that a certain proportion of cases of moderate "flooding" at the menopausal era, which spontaneously correct themselves, are of this type. It is scarcely necessary to urge that women should not be encouraged to hope for such a happy consummation, and that we should continue our present teaching that no other diagnosis should be entertained until that of malignancy has been excluded.

Diagnostic Curettage.—When the bleeding is sufficiently severe to cause concern in young women, and even more emphatically during middle age, the importance of diagnostic curettage cannot be too strongly urged. In no other way can the nature of the trouble be established. Especially distinctive is the finding of hyperplasia of the endometrium. It is only fair to say that, in a small proportion of cases, this diagnostic finding will fail us; but it is so common that a failure to demonstrate hyperplasia should at least lead to a suspicion of some unsuspected anatomic lesion, such as a submucous myoma or an intra-uterine polyp. Even making such an allowance, however, it appears probable that in a small proportion of cases the endometrium may be perfectly normal. Perhaps the nature of the endocrinopathy has something to do with these variations.

Only by diagnostic curettage can one exclude the existence of adenocarcinoma of the corpus. The far more common type of uterine cancer, i. e., squamous cell carcinoma of the cervix, can usually be readily diagnosed by inspection and palpation, with microscopic examination of biopsy sections in doubtful cases. In cases of bleeding in middle-aged women who are still menstruating, when diagnostic curettage is indicated because of the absence of more obvious causes of the hemorrhage, the benign hyperplasia will be found considerably more often than adenocarcinoma. The latter is much more apt to be noted in women who have passed the menopause.

In most cases, curettage will be followed by relief from the hemorrhage. In many cases this will be permanent, but in a large proportion, certainly in not less than one half, recurrence of the symptoms will be noted, perhaps almost immediately, though in other cases not until many months later. In some cases, the success of a curettage may merely reflect a coincident spontaneous curative tendency; in others, it may perhaps be interpreted as in some way altering the biochemical condition of the endometrium.

Organotherapy.—One hesitates to elaborate on this subject, because the results can scarcely provoke any great degree of enthusiasm. Often, however, they are distinctly gratifying, and certainly organotherapy is far more rational than drug medication. There is much reason to believe that the nature of the endocrinopathy differs in different cases. For example, thyroid extract is usually ineffective, but may occasionally give very striking results. In a girl of 12, on whom I performed a curettage for severe bleeding of three months' duration, which soon recurred, the administration of thyroid extract was followed by prompt cessation of the bleeding. When there are other manifestations of hypothyroidism, thyroid extract should by all means be resorted to, and will often be of great benefit.

In view of the common absence of corpora lutea in the ovaries in these cases, it is not surprising that corpus luteum preparations of one form or another have been advocated in this condition. Suffice it to say that the results have been no more satisfactory here than with ovarian therapy in general.[3] The results of mouth administration are notoriously disappointing, and no very potent extract for subcutaneous or intramuscular administration seems as yet available.

Posterior pituitary extract has also been employed in the treatment of this symptom, and in my own hands has yielded better results than any other form of organotherapy. Daily injections of the pituitary extract (1 cc.) may be given for at least six days, by which time beneficial results should have been noted if they are to occur. It is of course difficult to be sure, when improvement occurs, that it is not due to the action of the extract on the uterine muscle, rather than to any more specific endocrine mechanism.

Repeated Curettage in Recurrent Cases in Young Women.—When, as so commonly occurs, the bleeding returns, even after thorough curettage, the question as to the next step presents itself. In young women, in whom future childbearing is an important consideration, it is not always an easy one to settle. The remarkable development of radiotherapeutic technic in the last few years will impel some to urge these measures without further ado. It is probably true that, as a rule, careful radiotherapy by the expert will relieve the symptom without any unfortunate by-effects. There still seems, however, to be some uncertainty on such points as idiosyncrasy and possible later results on the ova, so that not a few gynecologists hesitate to resort to radiotherapy in young women, unless all other measures fail. A repetition of the curettage, perhaps several times, as the bleeding may demand, is preferred by some, tiding the patient over until the endocrine balance is restored. My own feeling is that, whenever possible, the patient or her family should be taken into our confidence, and the situation presented as fairly as possible. When this is done, my own experience has been that with most young patients, especially when the hemorrhage is not extremely profuse, the selection will be a repetition of curettage, with the slight attendant risk and inconvenience rather than even the slight uncertainty of radium therapy. There are, of course, certain social and economic factors which at times play an important part in arriving at a decision.

Radiotherapy, Especially in Patients at the Menopausal Age.—In women who have lived their reproductive lives, and in whom the matter of further child-bearing need not be considered or, at any rate, is distinctly subordinate to that of health, the indication is clear for radiotherapy. Here, indeed, we have the almost ideal indication for radium in gynecology, for menstruation can be checked promptly and with certainty. The methods, dosage and mechanism of this procedure need not be discussed in this paper.

---

[3] Novak, Emil: Endocrinology 6: 591 (Sept.) 1922.

Hysterectomy at Menopause Under Certain Conditions.—In uncomplicated cases, there would seem to be no reason for hysterectomy where radiotherapy is available, as it now is almost universally. In cases, however, in which there is some associated lesion indicating laparotomy, hysterectomy is a perfectly justifiable and, of course, an effective procedure, as far as cure of the bleeding is concerned.

26 East Preston Street.

SURGERY IN THE PRESENCE OF DIABETES *

E. STARR JUDD, M.D.
RUSSELL M. WILDER, M.D.
AND
S. FRANKLIN ADAMS, M.D.
ROCHESTER, MINN.

Two years ago,[1] we reported a low mortality rate following a series of operations on patients with diabetes. After two more years' experience in this type of work, we are now reporting the combined results of four years of effort to minimize the mortality rate in such cases. Between Oct. 1, 1921, and Oct. 1, 1925, 667 operations were performed on 497 patients; 363 of the operations were of a minor type, and 304 of a major type (tables 1 and 2). In the first group, two deaths occurred; in the second, eighteen. During the last three years in the Mayo Clinic, operations have been performed, regardless of the presence of diabetes, on the assumption that the diabetes itself, if properly controlled, would not increase the risk of operation. For three years, therefore, no patient has been refused necessary surgical procedures because of diabetes.

* One operative death.
† Two operative deaths.
‡ Three operative deaths.

In every case there was frank diabetes, but in the majority of cases it was mild. One hundred and eighty-one operations were performed in cases of moderately severe diabetes, and in eighty-two showing a severe form (table 3). According to one classification,[2] 119 cases were of the acute progressive type. In 158 cases the diabetes was associated with vascular lesions, in ninety-one with cholecystitis and pancreatitis, and in 199 with obesity. Fatalities occurred in about the same proportion in all these groups (tables 4 and 5). None of the deaths were directly attributable to diabetes. In only a few cases was there postoperative acidosis. In six cases carcinoma was the chief or contributing cause of death; pneumonia was the contributing cause in eight cases, and septicemia in three.

Severe	20	62
Total	304	363
Acute	15	104
Obese	89	110
Vascular	69	89
Doubtful	63	29
Interstitial	68	31
Total	304	363

The extremely low operative risk attending major operations on patients with diabetes reported for the two years 1922 and 1923 was not maintained during the next two years. This is probably largely a matter of chance, the averages for the four years representing more truly the surgical risk of such patients. The averages are considerably higher than those reported by the surgical staff of the clinic for operations in general, but low compared to the mortality rate of operations on patients with diabetes reported from other surgical clinics with wide experience. Undoubtedly, fewer cases of acute infections are seen in the Mayo Clinic than are seen in hospitals in larger cities. For example, in Bauman's[3] recent report, thirty-three patients required emergency surgical measures, while in our series there were only six. The surgical procedures in our series were, on the whole, as severe as those reported by other observers (table 1). It is significant also that the mortality rate was as high in the group of mild cases as in the severe.

Although modern methods of the treatment of diabetes eliminate the danger of acidosis and reduce considerably the susceptibility of the patient to infection, it is still possible that diabetes contributes to death in ways that we now have no means of measuring. As a rule, patients with diabetes who require operation are advanced in years. The youngest patient to die in our series was aged 51. The average age of all having major operations was 54 years. The average of those having minor operations was 47 years. Patients of this age with diabetes usually suffer from extensive degenerative lesions. Many of them have severe arteriosclerosis and many have coronary sclerosis and myocardial degeneration.[4] All of these factors add to the risk of operation, and it is unlikely that under the most favorable circumstances the surgical death rate in this group can ever be brought as low as that of any group of younger patients with fewer degenerative complications.

Table 4.—*Fatal Cases According to Classification of Diabetes*

Vascular	4	1
Obese	9	1
Doubtful	2	..
Interstitial	3	..
Total	18	2

Major amputations for gangrene of the extremities were performed in fifteen cases and resulted fatally in one case. The healing of the amputated stumps was very satisfactory. In order to insure a good blood supply to the stump, the amputation was high, and the blood sugar was maintained at approximately normal levels by the frequent injection of insulin.

In cases of gangrene limited to the toes, of the dry and nonadvancing type, two courses are open. The safest is amputation of the foot, but often the foot can be saved and the toe alone sacrificed. This offers a reasonable chance of conserving use of the foot and securing fairly rapid healing. The second course is medical treatment alone, which includes rest, stimulation of circulation, and the maintenance of the blood sugar at a low level by frequent injections of insulin. Exclusive medical management necessitates a long period of careful nursing and may be unsuccessful in the end. The decision as to which of these procedures is desirable in a given case will be influenced by the extent of the gangrene, the degree of obstruction of the blood vessels supplying the foot, the severity of the diabetes, and the economic condition of the patient. In a number of recent cases, we have observed somewhat better results in the healing of chronic ulcers and gangrenous areas following the direct application of insulin to the wound.

Three of twelve patients who were operated on for carcinoma of the rectosigmoid or descending colon died. Death was attributed to poor healing of the bowel at the point of anastomosis, leakage, and resulting peritonitis. The surgical risk in this type of operation is high under the most favorable circumstances, and the complication of diabetes with its attending arteriosclerosis is unquestionably extremely grave. The blood supply to the descending colon and sigmoid is always poor and, in cases of extensive arteriosclerosis, it is probably so poor that healing of the bowel is delayed and leakage inevitable. We can, we believe, reduce the risk in these cases by using more freely the multiple-stage operation and also by employing more free drainage of the wound at the time the resection is made.

FACTORS REDUCING MORTALITY

Methods of Treatment.—Several years ago, the plan was adopted at the clinic of placing all patients with diabetes, both surgical and medical, under one service in the hospital, and this has probably contributed largely to the lowering of the mortality rate following surgical operations. Patients are treated both before and after operation. The cooperation of the surgeon in postoperative management is obtained in the medical ward. There is no opportunity for the interruption of the precise diet and accurate administration of insulin that should precede and follow operation, and difficulties arising from a division of responsibility that were encountered before this plan was adopted are eliminated.

Purely surgical problems are left to the surgical staff for decision. These include, for example, the selection of the anesthetic. Ether has been the choice in a number of such cases,[5] and the mortality rate has not been greater than that with other anesthetics. From a medical point of view, ether is not a desirable anesthetic in cases of diabetes, but, as Fitz[6] has pointed out, the amount of ether used in individual cases in the Mayo Clinic is relatively small, and in certain cases the advantages to be gained from satisfactory anesthesia outweigh the danger of the anesthetic, as, for example, when the patient's complete relaxation permits a more rapid operation and thus lessens the severity of shock. Ethylene has been employed in many such cases, but thus far our experience has not been sufficient to conclude that it is any less dangerous than ether. Local anesthesia is obviously the most desirable, other things being equal. An unnecessary prolongation of an operation is extremely detrimental and is to be avoided.

Preoperative Treatment.—As Foster[7] has said, every patient with diabetes who is operated on should be regarded as a candidate for coma, and its prevention is better than the cure. Our practice is to prescribe a

TABLE 5.—*Details of Fatal Cases*

Case	Age	Sex*	Type of Diabetes	Anesthetic	Postoperative Days	Operation	Clinical Cause of Death	Necropsy Findings
1	51	♂	Moderate interstitial	Ether	4	Partial gastrectomy, appendectomy	Postoperative gastric obstruction and probable peritonitis	Refused
2	74	♂	Mild vascular	Ethylene and ether	19	Disarticulation of right great toe	Coronary sclerosis (?); pulmonary embolism (?); diabetic gangrene	Refused
3	57	♂	Mild interstitial	Ethylene	4	Cholecystogastrostomy	Bronchopneumonia; cancer of head of pancreas	Refused
4	54	♀	Mild obese	Cocaine	5	Tonsillectomy	Septicemia	Diabetes mellitus (clinical) with atrophy of pancreas (60 Gm); acute mitral endocarditis and terminal edema of brain
5	59	♂	Mild vascular	Ether and local	7	Suprapubic cystotomy; prostatectomy	Hypertrophy of prostate; myocardial degeneration; hypostatic edema of lungs; acute bronchitis; diabetes	Chronic cysto ureteropyelonephritis with acute exacerbation of phlegmons left cheek, neck and mediastinum, beginning gangrene; bronchopneumonia; acute pseudomembranous gastritis
6	55	♀	Mild vascular	Ethylene	11	Amputation through lower third of thigh	Staphylococcus septicemia; diabetic gangrene	Refused
7	71	♂	Moderate vascular	Ethylene and local	13	Drainage of perinephritic abscess, phlegmon of lower jaw and abscess of chest wall	Pyelocystitis; bacteremia	Refused
8	62	♀	Mild obese	Local ethylene and ether	34	Exploratory puncture below right scapula; radical amputation of left breast	Pneumonia; empyema; cancer of breast; metastasis	Amputation of left breast for cancer with pneumonia and empyema (healed), metastasis to lungs, pleura, mediastinal lymph nodes, parietal pericardium and omentum; infarct left lung; calcium left ureter with obstruction and dilatation of ureter; hydronephrosis, 3+; diabetes (clinical)
9	65	♂	Mild obese	Local	9	Colocolostomy	Pulmonary embolism; cancer of colon; diabetes	Recent colocolostomy for cancer of splenic flexure; jejunocolic fistula with pulmonary embolism (source?), diabetes (clinical), local peritonitis with moderate ileus, 2; cholecystitis with cholelithiasis
10	67	♀	Mild doubtful	Ethylene, ether and local	5	Finney pyloroplasty	Cancer of pancreas, pancreatitis and renal insufficiency	Cancer of pancreas with atrophy and metastasis to regional lymph nodes; recent excision and gastroduodenostomy for duodenitis with hemorrhage into stomach, duodenum, jejunum and local peritonitis; fatty changes in heart, liver and kidneys
11	57	♂	Mild obese	Ether and local	5	Anterior resection of rectosigmoid; temporary colostomy	Postoperative gangrene of wound	Postoperative gangrene of wound; formation of abscesses; arteriosclerosis
12	67	♂	Moderate doubtful	Ether	6	Cutting and avulsion of posterior root, gasserian ganglion	Bronchopneumonia	Section of posterior root of gasserian ganglion for trifacial neuralgia, with purulent bronchitis and bronchopneumonia; diabetes (clinical); cardiac hypertrophy, advanced coronary sclerosis
13	73	♂	Mild obese	Local regional	2	Prostatectomy; transfusion	Hypertrophy of prostate; myocardial degeneration	Suprapubic prostatectomy for hypertrophy and chronic infection of prostate with myocardial degeneration and cystitis; diabetes (clinical) with mild fibrosis of pancreas and fatty replacement; edema and congestion of lungs
14	69	♂	Mild obese	Ether	27	Herniotomy; removal of bilateral calcaneal spurs	Bronchopneumonia; staphylococcus septicemia	Refused
15	60	♂	Mild obese	Ethylene and ether	66	Temporary colostomy	Cancer of descending colon; pneumonia	Colostomy for cancer of descending colon with perforation; abscesses of left flank; metastasis to lymph nodes and liver; pneumonia with abscess formation; obesity; diabetes (clinical)
16	55	♂	Interstitial severe	Ether	6	Cholecystectomy	Lobar pneumonia	Obstruction of pancreatic duct by multiple calculi; destruction of pancreatic tissue; bilateral lobar pneumonia both lower lobes, fibrinopurulent pleuritis (1,500 cc left, 750 cc right); membranous enteritis of terminal ileum (30 cm)
17	59	♀	Mild obese	Ether	4	Appendectomy	Acute gangrenous appendicitis	Appendectomy and drainage for acute gangrenous appendicitis with generalized peritonitis; atrophy of pancreas, with diabetes (clinical); multiple diverticula of colon; cloudy swelling of kidney and liver
18	65	♂	Mild vascular	Nitrous oxide and oxygen, ether, and procaine	8	Partial thyroidectomy; suprapubic cystotomy for partial prostatectomy	Partial prostatectomy with pneumonia	Recent partial prostate [illegible] for can- [illegible] titis and [illegible] opneumo- [illegible] id follow- [illegible] d abscess [illegible] rophy of pancreas; arteriosclerotic atrophy of kidneys
19	65	♂	Mild obese	Field block	8	Permanent colostomy	Cancer of colon; colostomy with peritonitis	Colostomy for cancer of rectum with generalized peritonitis and terminal bronchopneumonia; metastasis to liver and mesenteric lymph nodes; thrombosis of portal vein
20	57	♂	Mild obese	Local	3	Removal of gland from right flank; transfusion; cholecystostomy	Cancer of pancreas; cholemia	Cancer of head of pancreas involving the ampulla of Vater; obstruction to common bile duct; general icterus; extensive pancreatitis; recent cholecystostomy

* In this column, ♂ indicates male; ♀, female.

diet containing 140 Gm. of carbohydrate, for a period of four days before operation, unless a surgical emergency necessitates less delay. This diet is richer in carbohydrate than that ordinarily given to patients with diabetes, but is probably desirable in surgical cases in order to build up a reserve of glycogen and thus offset postoperative acidosis. Insulin is used in the amounts necessary to control any glycosuria that may arise.

Postoperative Treatment.—When the patient returns from the operating room, he receives insulin and glucose. The latter is started by proctoclysis and later, when postanesthetic nausea has disappeared, is continued in the form of fruit juices and ginger ale by mouth. Enough insulin is given in repeated doses so that at least 75 Gm. of glucose is metabolized every twenty-four hours. All urine is tested for the presence of sugar and diacetic acid. The plasma carbon dioxide capacity is estimated whenever there is any clinical evidence of acidosis, and the slightest acidosis is combated vigorously.

CONCLUSIONS

1. Suitable preoperative and postoperative management, the proper selection and judicious administration of anesthetics, and surgical technic that avoids unnecessary trauma and delay, contribute greatly to reducing the risk of operation on patients with diabetes.
2. Patients with diabetes who undergo operations are very susceptible to acidosis, but the danger of such acidosis can be practically eliminated by proper treatment. Insulin is of great value in preventing acidosis, but does not replace other measures the value of which was proved before insulin was available.
3. The healing of operative wounds proceeds without any greater delay than usual, provided diabetes is rigidly controlled. The healing of chronic ulcers or indolent wounds may possibly be stimulated by the direct application of insulin to the wound. Most patients with diabetes, particularly those requiring surgical procedures, are advanced in years, are overweight, and are suffering from advanced arteriosclerosis and other degenerative lesions which independently make the surgical risk serious.
4. In view of these considerations, it seems to us that such patients should be referred for operation to one of the larger medical centers, where surgeons may cooperate with physicians who are experienced in the treatment of diabetes.

Psychologic Versus Traditional Aims.—Modern theory is opposed to the customary aims of physical training as given by many physical training directors so far as they are dominated by faculty psychology and an extreme confidence in formal discipline. General "obedience" (to commands), general power of "determination," of "order," of "exactness and precision," of "self-control," of "endurance," etc., cannot be developed to any great extent by gymnastics or any other phases of school activities. One may gain great powers of self-control, precision and determination in certain phases of school work without showing or possessing such agilities when outside the school environment in which they were developed. This again lessens the emphasis on formal physical training and strengthens the emphasis on purposive psychologic play and work. The progressive physical educator today is in favor of combining and unifying physical and mental education as one purposive system of activities having their own end, and he sees the tendency very strong in this direction in up-to-date schools. He is in favor of using as many instinctive play activities as possible, but he realizes that our highly artificial systems of schooling, with their present buildings, grounds, equipment and courses, will long resist the transforming tendencies.—Williams: Physical Education, pp. 5-6.

OCCURRENCE OF THROAT INFECTIONS WITH STREPTOCOCCUS SCARLATINAE WITHOUT A RASH *

FRANKLIN A. STEVENS, M.D.
AND
A. R. DOCHEZ, M.D.
NEW YORK

During the winter of 1924 and 1925, an epidemic of hemolytic streptococcus infection occurred in the Presbyterian Hospital. The infections were prevalent among the nursing staff as well as among the patients admitted to the wards, and consisted chiefly of scarlatina, acute throat infections and infections of wounds. This epidemic has afforded the opportunity to study two phases of streptococcus infections: first, the infection of wounds by individuals who chronically carry hemolytic streptococci in the nose and throat, and, second, the etiology of cases of acute tonsillitis and pharyngitis occurring among contacts with scarlatinal patients. We will confine this report to the study of the streptococci obtained from the throats of the nurses with scarlet fever and acute streptococus throat infections, since the material relevant to wound infection is to be published elsewhere.[1]

All the cases reported occurred among the nursing staff, which was housed in one building. The epidemic began with several cases of scarlet fever in December. Following the scarlatina were numerous cases of streptococcus angina. These cases were especially prevalent in January and February, but sporadic cases of scarlet fever and simple throat infection occurred until May. After the first few cases of scarlet fever were observed, practically the entire nursing staff of the hospital was tested for susceptibility to scarlet fever by the intracutaneous injection of toxin. The majority of the scarlatinal infections were early in the epidemic, so that we were unable to collect data concerning the relative susceptibility of persons with positive and negative reactions, but opportunity was afforded to determine several points relative to infections with *Streptococcus scarlatinae.* The questions to be answered were: 1. Can an anginal infection with *Streptococcus scarlatinae* occur without a rash? 2. If such infection does occur, does it occur in susceptible persons as indicated by the intracutaneous toxin test for immunity? 3. Do agglutination and toxin production correspond as a test of specificity for the identification of strains of hemolytic streptococcus during an epidemic of scarlet fever? 4. Are strains of hemolytic streptococci from cases of acute pharyngitis as closely related as the groups from scarlet fever and erysipelas? To settle the points in question, cultures of the throats were taken and the agglutination reactions and toxin production of the hemolytic streptococci obtained were studied.

METHODS OF STUDY

Cultures were made on blood agar, and a colony of hemolytic streptococcus was transferred to broth containing sterile strips of potato. If strains were diffuse in this medium, they were transferred to blood broth for storage, while the granular strains were transferred several times in this medium until they became diffuse. Two strains were selected from among the scarlatinal group (S III, S VIII) and two strains from the cases of pharyngitis for the preparation of immune agglutinating serums. The pharyngitis strains (T I, T IV) chosen did not produce scarlatinal toxin. Rabbits were immunized according to previously outlined methods, and each of the twenty-three strains from both the scarlatinal and the pharyngitis groups was tested for agglutination with each of the four serums obtained (serums S III, S VIII, T I and T IV). The technic of agglutination was that of Dochez, Avery and Lancefield.[2] Certain modifications, however, have been employed to facilitate the procedure; i. e., the streptococci for agglutination were grown in phosphate broth with sterile potato strips, centrifugalized, washed once in distilled water and resuspended in phosphate broth.[3] These modifications overcome numerous difficulties. Since certain strains of hemolytic streptococci occasionally become physically incapable of agglutination yet retain their antigenic specificity, the strains were tested for their ability to absorb heterologous agglutinin from serums S III and S VIII. We have found that such strains are capable of absorbing agglutinin for scarlatinal strains from scarlatinal serums, thus establishing antigenic similarities.[3] The dosage of the toxin[4] for skin testing had previously been determined. Control injections were made with toxin heated at 100 C. for two hours. The toxin production of the various strains was tested with filtrates of 2 per cent horse serum broth cultures in persons showing positive skin reactions with known scarlatinal toxin. These filtrates were studied with regard to the presence of heat labile toxin and for neutralization with scarlatinal antitoxic serum.

The data obtained in this study have been summarized in the accompanying table. The strains of streptococci have been arranged in the first column, with the source of each strain indicated by a letter, S (scarlatina) or T (acute pharyngitis). The second and third columns give the size of the skin reactions in centimeters with boiled and unboiled scarlatina toxin in the person from whom each strain was obtained. The fourth and fifth columns, respectively, show the presence of heat labile toxin and of toxin capable of neutralization with scarlatina antitoxic serums in the filtrates from cultures of the scarlatina and pharyngitis strains. The agglutination of the various strains with the serums scarlet I, scarlet VIII, throat I and throat IV is indicated by plus signs in the remaining columns. Under S I and S VIII, the column headed "absorption" shows whether the strains were capable (+) or incapable (—) of absorbing agglutinin from these serums for other scarlatinal strains.

COMMENT

The occurrence of scarlatina without rash has been suspected clinically for many years. Certain authors have noted the occurrence of severe angina without cutaneous manifestations among contacts with scarlatina.[5] Frequently these cases have been followed by severe nephritis.[6] Other instances have been noted in which scarlatina followed exposure to severe angina.[7] Aside from the rash, which varies greatly in intensity in scarlet fever, from the slightest punctate blush on the trunk and flexor surfaces in mild cases to the most vivid hue of red in the more toxic cases, it appears that we have no clinical criterion by which a severe streptococcus angina may be distinguished from scarlatina. Considering the variability of the rash in recognized cases of scarlet fever, there has been sufficient justification for believing that scarlatinal angina might occur without the usual cutaneous reaction.

Streptococcus scarlatinae is apparently a widely distributed organism. Williams[8] reports the presence of scarlatinal toxin producing strains in osteomyelitis, endocarditis, and in chronically inflamed tonsils in which there were none of the usual manifestations of scarlet fever. Since such strains have been isolated under these conditions, it is not surprising that five of the strains of streptococci obtained in cultures from the cases of acute pharyngitis occurring in this epidemic of scarlatina and angina showed both the agglutinative and the toxin producing properties of *Streptococcus scarlatinae.* This observation confirms the preceding clinical conception that scarlatinal angina may occur without a rash. How frequent these infections are cannot be ascertained from this series of cases, since all of the persons from whom cultures were obtained were scarlatinal contacts. Rosenow[9] has found strains of scarlatinal streptococci in acute follicular tonsillitis, but his series is too small to give an idea of the general incidence among nonscarlatinal contacts.

Perhaps the most important observation is that these cases of scarlatinal angina without rash have occurred among the personnel with negative Dick reactions. This leads us to believe that we must be careful in attempting to draw a strict analogy between scarlet fever and diphtheria. In diphtheria, in which the infecting organism is essentially a toxin producer and has little proclivity toward pyogenic manifestations, the Schick test is apparently an accurate index to the susceptibility of individuals to infection. We know that large amounts of scarlatinal antitoxin will prevent infection with *Streptococcus scarlatinae,* since both scarlatina and angina without a rash are rare among contacts immunized with antiscarlatinal serum. Among seventy-six contacts whom we have immunized with serum, scarlet fever occurred only once. When complications are established in scarlet fever with the scarlatinal streptococcus, this serum has no therapeutic effect. Apparently the streptococcus has both bacterial and toxic properties fully developed, and the Dick test, while indicating antitoxic immunity, is not an index of the amount of antitoxin necessary in the blood to prevent bacterial invasion. Rosenow, as well, has recently advanced the idea that the skin reaction is an index of antitoxic immunity and not of the immunity of the throat to streptococcus infection. Among a number of Dick negative individuals, a certain percentage will probably be immune to both the toxin and the bacteria.

It is interesting to observe that toxin production and agglutination with scarlatinal immune serums are closely parallel. The agglutination of the strains from the cases of nonscarlatinal pharyngitis indicate that there is no relation between strains of hemolytic streptococci causing acute throat infections.

CONCLUSIONS

1. Scarlatinal infection of the throat may occur without a rash.
2. This type of infection may occur in individuals showing negative skin reactions to scarlatinal toxin.
3. The Dick test is not a reliable index of immunity to such throat infections with *Streptococcus scarlatinae*.
4. In the series of cases observed, agglutination reactions with scarlatinal serum and toxin production are closely parallel.
5. There is no antigenic relationship between strains of hemolytic streptococci from acute streptococcus pharyngitis.

THE PATHOLOGIC PHYSIOLOGY OF EXPERIMENTAL GANGRENOUS PANCREATITIS *

LUCIA E. TOWER
CHICAGO

In this paper I present a brief preliminary report of a group of experiments, the object of which was, if possible, to obtain more information concerning the causes and the nature of the violent toxemia occurring in acute hemorrhagic pancreatitis. Ultimately, it was hoped, a more rational and effective treatment of the disease might be evolved than is now generally employed.

No attempt will be made here to discuss the literature on acute pancreatitis, or to describe the clinical manifestations of the disease. For this information the reader is referred to the recent very inclusive paper by Moynihan.[1] Suffice it to say that almost every conceivable method by which the pancreas could be seriously injured has been utilized to reproduce in animals the clinical picture of acute pancreatitis; all that is necessary is that a sufficient amount of pancreatic tissue be suddenly so devitalized that an extensive necrosis and autodigestion of the gland will occur.

The most hotly contested questions between experimenters on this disease pertain at present to the rôle played by bacteria in its etiology and symptomatology. Deaver, Arnsperger and Maugeret are the principal proponents of the theory that the prime factor in the causation of the disease is an infection reaching the pancreas by way of lymphatics from neighboring organs. Others consider that the entrance from the duodenum of bacteria (which are presumed to be normally absent) into the pancreatic ducts under certain conditions may activate intraductally the pancreatic enzymes, which will then produce a severe pancreatic lesion. Those who adhere only to the bile theory of the etiology of acute pancreatitis manage to disagree as to the importance of infected versus noninfected bile. It is far from a settled matter whether the toxemia of acute pancreatitis is dependent on the absorption of protein split products from the necrosing gland into the general circulation and whether bacteria play any rôle in the formation of these substances, or on the diffusion of ferments into the peritoneal cavity with the absorption of poisonous products of their action on the peritoneal tissues, or on the absorption into the general circulation of these ferments. No one has, as far as I know, considered the possibility of a toxemia occurring as a result of a severe local injury by these protein split products, acting presumably on the intestinal musculature and probably also on that of the vascular system. The experiments cited here strongly indicate that such may be the mechanism by which the toxemia is produced. These experiments were commenced with the idea of producing, if possible, a strictly aseptic, typical pancreatitis, and if this was not possible, of studying the rôle of the organisms that were found.

METHODS

Dogs were used throughout most of the work; all experiments were done with complete morphine-ether anesthesia. An absolutely typical picture of acute hemorrhagic pancreatitis was produced by the simple process of tying off all the blood supply to a sufficient amount of the gland. A similar method was used by Blume[2] in 1897 and by Katz and Winkler[3] in 1898. The anatomy of the dog's pancreas is such that the head and tail are thus very easily rendered gangrenous, the body with difficulty so. The head, tail and body of the gland each represent approximately one third of its total weight. When it was desired to injure the body of the pancreas in addition to the head and tail, several methods were used; namely, injection of bile through the pancreatic duct, crushing the body with forceps, or tying multiple ligatures through its substance. In the bacteriologic work, more than ordinary precautions were taken to insure operations and necropsies as aseptic as possible. Necropsy cultures were taken immediately after death, or, preferably, the animals were killed when moribund if death seemed imminent. All cultures were taken on enriched mediums. In one group of animals an attempt was made to produce the usual toxemia of acute pancreatitis by the removal of aliquot portions of the pancreas and replacing them in the abdomen, carefully wrapped in the omentum. That this failed is highly significant.

RESULTS

The extreme variation in the symptoms and pathologic conditions developing from the same identical procedure in different animals is very striking. By the methods described, all the different pathologic conditions characteristic of acute pancreatic affections in the human being have been reproduced, from complete gangrene to the formation of large, single pseudocysts. The one notable difference was the absence of fat

necroses in about two thirds of the animals. I have no explanation for this. They are, however, occasionally reported absent by clinicians.

The mortality statistics which follow are of considerable interest:

> One third of the gland (head or tail) destroyed (i. e., all blood vessels tied off and the portion thus isolated left in situ): Four out of eleven animals (36 per cent) died in from twenty-four to seventy-two hours of a typical acute hemorrhagic pancreatitis.
>
> Two thirds of the gland destroyed (head and tail): Fourteen out of twenty-five animals (56 per cent) died in from eighteen to 120 hours of a typical pancreatitis.
>
> More than two thirds of the gland destroyed: Of six animals, all died in forty-eight hours or less.
>
> One third of the gland removed and wrapped in the omentum: Six animals, no deaths.
>
> Two thirds of the gland removed and wrapped in the omentum: Three animals, no deaths.
>
> Entire gland from another animal wrapped in omentum: One animal, survived.

The symptoms indicative of the amount of toxemia varied also in much the same way. Unmistakable signs of a severe toxemia were present in 80 per cent of the animals with one third of the gland destroyed, and in all of those with two thirds or more destroyed. Of those animals with one third removed to the omentum, none showed more than the slightest evidence of malaise; all those with two thirds or more removed showed a moderate degree of general indisposition.

The number of animals presenting extensive walling-off adhesions of the omentum and the neighboring structures to the pancreas at necropsy was somewhat higher for those that recovered. This may be either the cause of or the effect of the recovery or both.

All attempts to produce a sterile pancreatitis failed. Organisms were always found in one or more of the cultures taken from the peritoneal exudate, the gangrenous gland, localized abscesses, etc. Twenty-three sterile necropsies were performed; in only two of these were all cultures negative. These were from animals in which part of the pancreas had been removed to the omentum, where it had become firmly encysted, and there was no toxemia or any of the pathologic findings of acute pancreatitis. Although organisms were always found, the impression received from the experiments was that the presence of bacteria in the acutely inflamed tissues was merely incidental, in that the reaction involved was one due to a violent toxemia which so reduced the vitality of the tissues that the nonpathogenic bacteria were able to gain a temporary foothold, which they lost rapidly as the toxemia disappeared. The fact that such organisms could be demonstrated in the peritoneal exudate of an animal well on the road to recovery, with no evidence whatever of peritonitis (i. e., the ordinary infectious type), indicates their probable relative unimportance in the picture, unless it be, as we now have no method of determining, that their mere presence in the tissues and exudate adds to the toxemia through products of their growth. This consideration puts the problem in the same class with that very difficult one of the rôle of bacteria in the toxemia from acute intestinal obstruction.

Sixteen bacteriologic analyses of fresh pancreas tissue removed sterilely at operation showed the presence of bacteria in all except one. It would appear from this that bacteria are normally present in the pancreas, presumably in the ducts.

In general, those organisms found in the fresh pancreas and in the tissues and exudate at necropsy were of a nonpathogenic variety, and were those organisms common to the upper gastro-intestinal tract. Various staphylococci, occasionally nonhemolytic streptococci, *B. subtilis, B. coli,* diphtherioid bacilli, sarcinae, yeasts and molds were the most frequent ones found.

COMMENT

Observation of the facts that the entire clinical and pathologic picture and the mortality rates are so very different when a given amount of pancreas tissue is allowed to autolyze completely wrapped up in the omentum from those obtained when it is left in situ; that the clinical picture of a typical case of acute pancreatitis so closely resembles that of an acute upper intestinal obstruction that it is often impossible to differentiate them; that there is a greater tendency on the part of the animals to recover when the omentum and other adjacent structures become adherent to and wall off the necrosing pancreas, and the distinct indications that the bacteria present in the inflamed tissues and exudates of the abdominal cavity are the result of and not the cause of this inflamed condition, leads to the suggestion that the symptoms of acute pancreatitis may be dependent on the liberation of some toxic product from the necrosing pancreas tissue, which, acting locally on the gastro-intestinal tract, and principally the upper gastro-intestinal tract, so interferes with its normal function as to produce a generalized toxemia of gastro-intestinal origin, probably of the nature of that associated with a paralytic ileus. The possibility that the omentum has some detoxifying power must also be considered as an explanation of the findings here reported, but this seems a less likely explanation. I shall not attempt here to give any actual figures as to the number of cases gleaned from the literature in which complications have been noted in man or in animals, occurring with acute pancreatitis, in which a disturbance in gastro-intestinal motility is indicated. Obstipation is a not infrequent symptom. In my own series of animals, three have died of intussusception in the jejunum, and one of acute dilatation of the stomach. Since the method I have used to produce pancreatitis involves a minimum of trauma, these complications could probably not be explained on that basis. The finding at necropsy of more or less dilatation of part or all of the gastro-intestinal tract, especially the duodenum, but sometimes only of those loops of bowel near the pancreas, is almost the rule, and not infrequently I have noted a loss of the normal elasticity of the intestinal walls so that they stretch like dead rubber. The mere intensity of the peritoneal reaction in acute pancreatitis would indicate a local irritation that has certainly been overlooked far too much in the past. Might not the extreme splanchnic congestion, the very low blood pressure, and the hemorrhagic exudate be the result of a local paralysis of the vascular musculature?

If this premise concerning the origin of the toxemia in acute pancreatitis approaches the truth, it opens up those new lines of therapy which are proving effective in the treatment of acute intestinal obstruction, as possibilities to control the toxemia of acute pancreatitis. Modifications of the methods advocated by Haden and Orr, the Portises and others may prove more effective than the present one of putting a drain in the pancreas. Experiments designed to test out these therapeutic methods in experimental acute pancreatitis are being conducted at present and will be reported in a later paper, as will also a group of experiments in progress on the blood chemistry changes in acute pancreatitis.

Cook County Hospital.

LIVER FUNCTION TESTS

A COMPARATIVE STUDY OF FIVE METHODS IN ONE HUNDRED CLINICAL CASES *

SAMUEL S. BERGER, M.D.
MILTON B. COHEN, M.D.
AND
J. J. SELMAN, M.D.
CLEVELAND

On our service at Mount Sinai Hospital during the last three years we have performed liver functional tests as a routine. The present report gives the results of 100 cases in which five tests were performed simultaneously, or within an elapsed time of forty-eight hours, which were done in the last year. The tests performed were the van den Bergh test,[1] the Widal[2] test (hemoclastic crisis), Rosenthal's[3] test, examination of the urine for urobilin and urobilinogen, and examination for bile salts in the urine.

THE VAN DEN BERGH TEST

Both the qualitative, which is divided into the immediate direct, biphasic direct, the delayed direct and the indirect, and the quantitative tests were employed. The quantity of bilirubin was expressed in units, the unit being a concentration of 1 in 200,000. We regarded 0.5 unit as the upper limit of normal.

Table 1.—*Results Obtained in a Negative and a Positive Widal Test*

A Positive Widal		Check on Same Patient
Before giving milk	14,400	10,800
30 minutes after	12,400	11,000
60 minutes after	13,400	10,400
90 minutes after	11,800	11,600
120 minutes after	12,600	10,800
A Negative Widal		**Check on Same Patient**
Before giving milk	7,800	7,800
30 minutes after	10,200	7,800
60 minutes after	9,000	7,600
90 minutes after	9,600	7,800
120 minutes after	9,400	7,600
150 minutes after	11,000	77,800

THE WIDAL TEST

We modified the original Widal technic by determining the changes in white cell count at thirty minute, instead of fifteen minute, intervals, following the ingestion of 200 cc. of milk given in the morning on an empty stomach or, in a few cases, after a fast of five hours. We have regarded a fall in the count of 1,000 cells within a three hour period as positive, and have designated it as one plus, adding another plus for each additional drop of 500 cells. The leukocyte counts were all done by the same person. Checks were made of the margin of error, using different pipets and making several counts on the same person at thirty minute intervals without having administered the milk. The average variation was 200 cells. The largest was 800 cells. Tests were also run on twenty-five normal persons—nurses and laboratory technicians—to check the method. All were negative. An example of the check used is given in table 1, showing the results obtained in the case of a negative and a positive Widal.

ROSENTHAL'S TEST

We have followed the modification of Rosenthal's original methods, which were described by Bogen,[4] and by Bloom and Rosenau,[5] and have taken the reading one hour after injection of the dye. Retention after one hour has been considered positive.

EXAMINATION OF URINE FOR UROBILIN AND UROBILINOGEN

For urobilinogen, Ehrlich's reagent[6] was used, and the determinations were made on freshly voided warm specimens. For urobilin, Schlesinger's[6] method was followed. We have found that this test is more easily read after standing for twenty-four hours.

BILE SALTS IN THE URINE

The Hay test[6] for the determination of bile salts in the urine has been used by us with especial attention to the following details: It should be performed on the morning urine, as this is the most concentrated sample in the twenty-four hours. It is important to use a clean beaker, filtered, freshly voided urine, and dry, finely powdered sublimed sulphur. The beaker should be on a level with the eyes, and good light is necessary. The test is based on the diminution of the surface tension of the urine in the presence of bile salts. If the test is positive, the sulphur particles will begin to fall to the bottom of the beaker immediately. The rapidity with which the sulphur particles are falling to the bottom of the beaker may be taken as a rough index of the amount of bile salts present. Studies of the bile salts content of the blood were made by Pettinkofer's method,[6] but its significance will not be discussed here.

The cases have been divided into four classifications: group 1, cases of liver disease with jaundice, nineteen observations; group 2, cases of liver disease without manifest jaundice, six; group 3, cases with clinical conditions in which liver disease was suspected but not clinically demonstrable; group 4, cases with clinical conditions in which liver disease was unsuspected, thirty-eight.

Group 1.—*Cases of liver disease with jaundice, nineteen observations.* This group consists of fourteen patients with the following diagnoses: There were seven cases of toxic jaundice, five of which were catarrhal, one followed arsphenamine therapy, and one which occurred during pneumonia; four cases of obstructive jaundice due to growth in the pancreas or ducts (operation); two cases of cholelithiasis (in which operation was performed); one with stone in the common duct with incomplete obstruction, and one case of primary carcinoma of the liver (necropsy).

Group 2.—*Cases of liver diseases without manifest jaundice, six observations.* Here there are six cases with the following clinical diagnoses; one case of pernicious anemia; one of Banti's disease; one of splenomegalic type of cirrhosis (in which operation was performed); one of secondary carcinoma of the liver; one of cardiac failure with enlarged liver and questionable jaundice, and one of enlarged liver and cholecystitis.

Group 3.—*Cases with clinical conditions in which liver disease was suspected but not clinically demonstrable.* In this class we have included cholecystitis, in which there is a direct inflammatory reaction in the liver; and the acute infectious fevers and toxemias in which in all the organs, including the liver, there is cloudy swelling and parenchymatous degeneration.

Group 4.—*Cases with clinical conditions in which liver disease was unsuspected, thirty-eight observations.* In this group we have included those chronic conditions commonly seen in medical wards.

Table 2 shows the result of these tests in cases of toxic jaundice. As these are all cases with jaundice it is, of course, obvious that the quantitative van den Bergh test should be positive in all, since this test is merely a measure of the circulating bilirubin. The Widal test is also positive in all cases. This also is not surprising when one remembers that in toxic jaundice there is marked injury to the polygonal liver cells, and it is these cells that are supposed to perform the protein function of the liver. The dye test was positive in all except one case which was seen during convalescence. In one other case, namely, case 2, the dye test, which had previously been positive, became negative, while the Widal and van den Bergh tests were still positive. Urobilin or urobilinogen appeared in the urine in all cases except during the obstructive phase of catarrhal jaundice. It was at this period chiefly that bile salts also appeared.

Table 2.—*Results of Tests in Cases of Liver Disease with Toxic Jaundice (Nine Observations)*

Case	Diagnosis	Van den Bergh	Widal	Dye	Urobilin	Bile Salts in Urine
2	Catarrhal jaundice	10 0	..	3 5%	—	..
		2 5	..	16 0%	..	..
		9 71	..	—	—	—
8	Pneumonia with toxic jaundice	....	..	......	..	..
4	Catarrhal jaundice	10 0	..	10 0%	—	—
6	Catarrhal jaundice	20 0	..	18 0%	..	..
82	Catarrhal jaundice	25 0	..	20 0%	..	—
99	Catarrhal jaundice defervescence	1 0	..	—	..	—
107	Arsenical poisoning; acute systemic syphilis	15 0	..	10 0%	..	..
Percentage positive......		100%	100%	77.8%	66 6%	55 5%
Percentage negative......		0	0	22.2%	33 4%	44 5%

Table 3 shows the results of these tests in cases of jaundice due to stone or tumor. It will be noted again that the van den Bergh test shows an increase in circulating bilirubin in all cases. The Widal test is positive only in those cases due to stone, and in the case of primary carcinoma of the liver, with the exception of one slight reaction, in case 104, after there had been complete obstruction due to tumor at the head of the pancreas for ten weeks. It was persistently negative in all of the observations in jaundice due to tumor obstructing the ducts, with the exception noted above. This is the one laboratory finding which in our experience has enabled us to differentiate between jaundice due to growth obstructing the ducts and that due to stone or catarrhal jaundice in the stage of complete obstruction. The dye test was not always positive. In the cases of obstructive jaundice it generally paralleled the bilirubin retention, except in two cases of cholelithiasis and cholecystitis proved at operation, in which it was negative. Urobilin and urobilinogen were present in all except one case when bile reached the intestine, but were absent in all cases during the completely obstructive phases. Bile salts were found in all cases except the two previously mentioned in which the dye test was negative, and late in case 104, when, after ten weeks of complete obstruction, the bile salts disappeared.

Table 3.—*Results of Tests in Cases of Liver Disease with Jaundice Due to Stone or Tumor (Ten Observations)*

Table 5.—*Results of Tests in Cases with Clinical Conditions in Which Liver Disease Is Suspected (Thirty-Seven Observations)*

Van den Bergh		Widal		Dye		Urobilin		Bile Salts	
Pos	Neg	Pos.	Neg.	Pos	Neg	Pos	Neg	Pos	Neg
37.9	62 1	59 4	40 6	16 2	83 8	32 5	67 5	48 6	5 14

Table 4 shows the results in the cases in group 2. The van den Bergh test was positive in 83 per cent, the Widal in 50 per cent, the dye in 33 per cent, urobilin and urobilinogen in 63 per cent, and bile salts in 33 per cent. The dye test and the bile salt test were the only ones not positive in the majority of the cases.

Table 6—*Results of Tests in Cases with Clinical Conditions in Which Liver Disease Was Unsuspected (Thirty-Eight Observations)*

Van den Bergh		Widal		Dye		Urobilin		Bile Salts	
Pos.	Neg	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.	Pos	Neg
42 1	57 9	39 4	60 6	10 5	89 5	5 5	94 5	23 6	76 4

Table 7—*Results in Groups 2, 3 and 4*

	Van den Bergh	Widal	Dye	Urobilin	Bile Salts
Group 2. Liver disease without jaundice	83 3	50 0	33 3	66 6	33 3
Group 3. Suspected liver disease	37 9	59 4	16 2	32 5	48 6
Group 4 Unsuspected liver disease ...	42 1	39 4	10 5	5 5	23 6

Table 5 comprises the observations in group 3, and table 6, those in group 4.

Table 7 comprises the results of these tests in group 2 (liver disease without jaundice); group 3 (suspected liver disease), and group 4 (unsuspected liver disease).

SUMMARY

In group 1-A, toxic jaundice, all the tests were positive. In group 1-B, obstructive jaundice, in all cases due to stone, all the tests were positive; in all cases due to tumor of the pancreas or biliary ducts, all the tests were positive in each case except the Widal, which was negative in all.

In group 2, clinical liver disease without jaundice, the tests did not yield uniformly positive results. In no case were all positive; in two cases, four of the five were positive, and in the remainder, from one to three were positive.

In group 3, cases in which liver disease was suspected but not clinically demonstrable, no case yielded positive reactions to more than three of the tests; in some, three were positive, but in the majority, only one or two were positive.

In group 4, cases in which no liver injury was suspected, the results were similar to those of group 3.

COMMENT

In any attempt to evaluate these tests, an explanation must be found for the relatively high percentage of positive findings for all of them in groups 3 and 4, as shown in table 7. There are two possibilities, namely:

1. That none of these tests are specific for liver dysfunction.
2. That these tests are specific for liver dysfunction, but that many persons have latent liver damage or liver dysfunctions that are transient and are undetectable by ordinary means.

Credence for the first possibility can be given only if these tests are positive in perfectly normal persons. The persons usually employed for controls are hospital patients who may well have latent injury regardless of the clinical diagnosis. To check this hypothesis we have performed Widal tests on twenty-five normal volunteers, nurses and laboratory technicians who have not been ill for a period of twelve months and who have never had any affections of the appendix, gallbladder, liver or its ducts. In each instance the test was negative. We are able to conclude, therefore, with Feinblatt, who found negative tests in each of eighty medical students, that the Widal test is not positive in normal persons. Rosenthal states that in normal persons, if 5 mg. of phenoltetrachlorphthalein per kilogram of body weight is injected intravenously, all is eliminated in one hour, but he regards from 2 to 3 per cent as within the normal limit.

The second hypothesis seems, therefore, to be the more logical one. These patients were ill in bed, and latent liver injury may have been present. With this in mind one must be careful in the choice of normal controls and must not use cases such as those of the Mayo Clinic series,[7] as in our experience cases with chronic infectious processes do give positive reactions to some of these tests.

CONCLUSIONS

1. It is important to bear in mind that these tests represent different functions of the liver. Any one or more or all of these functions may become impaired. Again, one or more of these functions may escape injury. Therefore the various tests do not give parallel results. When we attempted to separate clinical cases into groups of liver disease or no liver disease by means of any one of these tests, unsupported by other clinical evidence, we were unable to do so.
2. When all the tests were positive, we were dealing with liver disease, clinically of the most severe type; namely, toxic jaundice.
3. When all tests were positive except one, namely, four positive and one negative, clinical liver disease was present, usually of a chronic type, such as that seen in Banti's disease or pernicious anemia and cirrhoses.
4. In every case in which all the tests were positive except the Widal, there was obstructive jaundice due to tumor. This finding is of great value in differential diagnosis.
5. When only three tests were positive it was impossible to correlate the findings with the clinical picture, as there were many cases in which liver disease was suspected which did not give positive reactions to more than one or two tests and, conversely, there were many cases in which liver disease was unsuspected which gave as many positive results.
6. At present they are of use chiefly in the differential diagnosis and in following the progress of a given case.[8] The greatest amount of information can be gained by doing all the tests simultaneously and repeating them often.

SIGNIFICANCE OF THE BLOOD CHEMICAL CHANGES IN PERTUSSIS

THERAPEUTIC INDICATIONS *

JOSEPH C. REGAN, M.D.
AND
ALEXANDER TOLSTOUHOV, M.D.
BROOKLYN

Important advances have been made in the study of whooping cough in recent years, along the lines of bacteriologic and serologic research. The etiologic relationship of the bacillus described by Bordet and Gengou has been more definitely established, and Bordet has applied his fundamental work in immunology to the development of a complement fixation test for the diagnosis of the disease, which may permit the recognition of the abortive, rudimentary or atypical forms. A vaccine prepared from *Bacillus pertussis* has been utilized in prophylaxis and treatment, but vaccine therapy has given such inconstant results that a considerable difference of opinion exists as to the curative value that it may possess. A mixed vaccine apparently has a definite prophylactic value against the bronchopulmonary complications. Recently, much interest has been aroused in the roentgen-ray treatment of the disease, described by Bowditch.[1] Several favorable reports relative to its use were made at first, but the discussion which followed the recent paper by Smith and his associates[2] brought up the pertinent facts of the effect of the treatment on the thyroid and thymus as well as the value of the remedy. The recent report of Faber and Struble was not favorable.[3] The mode of action of the roentgen ray was thought at first by

Bowditch to be the result of an effect of the rays on the tracheobronchial adenitis and later by Smith and Bowditch surmised to be due possibly to an influence on the calcium content of the blood, although they had no opportunity to make actual determinations. It is important to recall here, in view of the results we are reporting, that Hussey[4] found that the roentgen ray induced a condition of alkalosis in rabbits, as confirmed by Victor Myers[5] in clinical cases of carcinoma treated by the roentgen ray.

In a recent paper,[6] a brief outline of the results obtained in an analysis of 200 specimens of blood from pertussis cases was made. Attention was drawn to two alterations detected with considerable constancy; namely, a diminution of the total inorganic phosphorus content of the plasma, and a change in the hydrogen ion concentration. We now present further data relative to the blood chemical findings of this disease, giving the results in somewhat more detail, and outline briefly the apparent effect of the administration of alkaline salts on the chemical changes of the blood and on the course of the disease.

Our study was carried on during the summer and early fall of 1924 and 1925. There were more than 111 patients with mild, moderate or severe pertussis in the group, the ages ranging from 4 months to 12 years, 78 per cent being over 3 years of age.

Table 1.—*Blood Chemical Determinations in Pertussis Before Treatment*

	Normal Blood Values	Blood in Pertussis: No. of Determinations	Average Value	Range: Minimum	Range: Maximum
Hydrogen ion concentration	7.35-7.40	37	7.29	6.95	7.45
Phosphorus (inorganic).....	4.5-7.0 mg.	37	2.4	0.7	3.6
Calcium........................	10.5-11.5 mg.	32	10.5	8.5	13 3
Carbon dioxide..............	53-77 % by vol.	20	56	42	68
Urea..........................	20-35 mg.	25	27	18	37
Uric acid......................	2-3 mg	31	3.3	1.2	5.5
Creatinine....................	1-2 mg.	27	1.1	0.9	1.3
Sugar..........................	68 mg.	23	65	50	76

BLOOD CHEMICAL DETERMINATIONS

The investigations included the following analyses: hydrogen ion concentration, 146; inorganic phosphorus, 211; calcium, 58; carbon dioxide, 83; urea, 38; uric acid, 59; creatinine, 44; sugar, 43; total determinations, 682.

The blood was taken in the morning before breakfast, and the examination was carried out promptly, or the blood was stored for a short period in the icebox after transportation to the laboratory. The usual precautions necessary in collecting specimens for determinations of the p_H were utilized, such as short compression of the arm, the avoidance of air entering the syringe, and the injection of the blood into paraffin coated bottles under liquid petrolatum.

Values for Urea, Uric Acid, Creatinine and Sugar.—The determinations gave values which, on the average were within the normal range for urea, creatinine and sugar. The uric acid figures on the average were slightly above the high normal values for this constituent.

Carbon Dioxide Content of Plasma.—The average value for carbon dioxide was in the lower part of the normal range. Thus, in twenty moderate or very severe cases before any treatment, the average figure was 55.3 per cent by volume, while in twenty-four mild untreated cases the average figure was 60.8. Obviously, there was no definite pathologic change, as the patients were all children, with one exception.

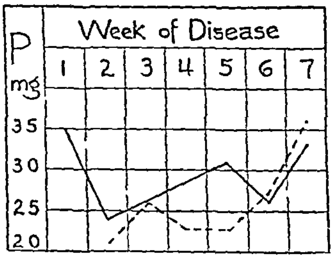

Chart 1.—Inorganic phosphorus in blood in pertussis. solid line, treated cases of moderate and severe pertussis; broken line, mild and untreated cases.

Phosphorus Content.—The total inorganic phosphorus content of the serum showed a diminution which was so constantly encountered that, with the alteration in p_H previously mentioned, we have called it characteristic (table 1).

When the first low values for phosphorus were encountered, the possibility of a rachitic basis was considered. As further study was made, we felt that this possibility could be dismissed, for several reasons. As mentioned before, more than 78 per cent of the children were over 3 years of age or beyond the period when active rickets is so common; none of the patients except a few of the infants had any active signs of rickets; the accentuation of the diminution of the phosphorus was entirely unrelated to the age of the patient, bearing a relation only to the stage and duration of the disease; the rise in inorganic phosphorus occurred without any of the classic antirachitic means of treatment, and was induced in a number of cases, especially in those in which the disease was treated early, with a remarkable rapidity, as will be shown later by the administration of alkalis. Moreover, the hydrogen ion concentration of the blood is lowered, a condition not spoken of in rickets.

Beginning in the latter part of the catarrhal stage of pertussis, a lowering of the total inorganic phosphorus of the blood occurs (1.6, 1.7 and 2.5 mg. in three cases), which is already well established in the very first week of the paroxysms (1.5, 1.7, and 2 mg. in four cases).

Table 2.—*Blood Chemical Determinations in Pertussis in Relation to Treatment* *

	No. of Determinations	Before Treatment	No of Determinations	During Treatment	No. of Determinations	After Treatment
Hydrogen ion concentration	37	7.29	46	7.37	25	7.43
Phosphorus, total inorganic	37	2.4 mg.	56	2.6 mg.	47	3.1 mg.
Calcium........................	32	10.5 mg.	13	9.9 mg.	9	10.5 mg.
Uric acid......................	11	3.4 mg.	14	3.3 mg.	7	3.9 mg.
Carbon dioxide..............	20	56 % by vol.	22	52 % by vol.	18	57 % by vol.

* This table shows the changes that occur in the blood under alkali treatment.

In moderate and severe types of the disease treated by alkalis, there is an average rise in the third week in phosphorus, which continues in the fourth and fifth weeks, with a slight fall in the sixth week, and the highest level in the seventh week (chart 1). In mild cases untreated by alkalis, there is on the contrary a lower average curve, so that after a temporary rise in the third week, the average continues low in the fourth and fifth week, beginning to rise in the sixth week (chart 1).

[6] Regan, J. C., and Tolstouhov, Alexander: Characteristic Changes in the Blood Chemistry in Whooping Cough, J. A. M. A. **86**: 181 (Jan. 16) 1926.

Hydrogen Ion Concentration.—The hydrogen ion concentration of the blood was determined in the plasma taken with usual precautions and was examined by either or both the electrometric or colorimetric method. The results show a change in the p_H which has been very accentuated in some analyses. The change in the p_H in the first five weeks of the disease (chart 2) in treated cases (moderate and severe type) corresponds, although it is less accentuated, almost exactly with the change in the inorganic phosphorus in the same period, and this analogy carries with it an importance that will be mentioned later. It will be observed here again that, while the p_H curve in cases before treatment is a gradually rising one, the elevation is more accentuated in those under treatment, while in those in which treatment has been completed, the curve is suddenly elevated to a pronounced degree in the third and fourth week.

Calcium Content.—The normal calcium content of the serum of infants and young children averages, according to Howland and Kramer,[7] between 10.5 and 11.5 mg., and according to de Wesselow,[8] who includes general grouping apparently of all ages, as between 9 and 11 mg. per hundred cubic centimeters. In the cases of petussis studied, the calcium determinations carried out in fifty-eight specimens of serum gave figures showing some variations, but averaging before treatment 10.5 mg. in thirty-four analyses. In only eight, or 23 per cent, was there more than 1 mg. less than the normal value as given by Howland and Kramer, and only two, or 5.3 per cent, of these eight were below the normal range according to de Wesselow's figures. This variation of 1 mg. in a few cases is not significant as an alteration because of possible error in determinations. Therefore, we do not consider the calcium content altered in any constant way in pertussis, although it is possible that slight changes may occur as the result of shifting of calcium in connection with the characteristic phosphorus and p_H alterations.

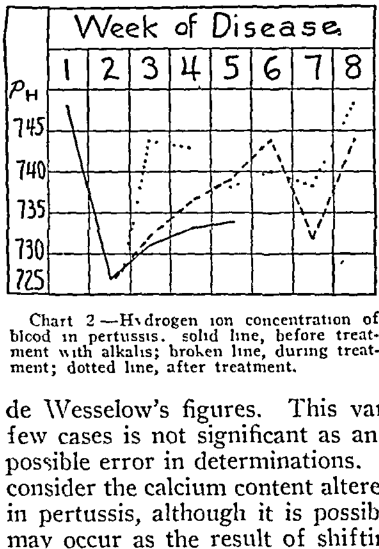

Chart 2.—Hydrogen ion concentration of blood in pertussis. solid line, before treatment with alkalis; broken line, during treatment; dotted line, after treatment.

SIGNIFICANCE OF BLOOD CHEMICAL CHANGES

As the carbon dioxide content of the plasma showed a normal range, and yet was associated with a lowering of the hydrogen ion concentration and of the inorganic phosphorus, we consider it proved that there occurs in pertussis an acidosis of an uncompensated type (type 6, Van Slyke classification),[9] which has as a cause the accumulation or increased concentration of free carbon dioxide in the blood.

Many of the symptoms so prominent in the clinical picture of pertussis may be very well correlated to conform with this point of view. The peculiar and unique character of the paroxysms surely interferes considerably with the ventilation of the lungs at this time, and is probably associated with increased alveolar air tension, an assumption warranted also by reason of the well nigh constant occurrence of some degree of parenchymatous emphysema in patients with pertussis. The alterations in the tracheobronchial tract, still poorly understood, may also enter potentially as factors. Vomiting and convulsions are frequent symptoms, and in many instances the gastric troubles occupy such a conspicuous place in the clinical syndrome that they have given rise to the description of a gastric form of the disease, in which gastric intolerance is a conspicuous symptom. It is our belief that the vomiting in the disease is a compensatory process which endeavors by elimination of very acid gastric contents to maintain the normal acid base balance.

Theoretically, if an acidosis of an uncompensatory type, as described, exists, the supplying of the organism with alkaline salts might restore the ratio between bicarbonate and free carbon dioxide. Practically this occurs.

In our cases, the hydrogen ion concentration of the blood has been changed to normal or to the alkaline side of normal (table 2) by the administration of various combinations of bicarbonate, calcium carbonate, and magnesium oxide. In such instances we have observed, accompanying the change in reaction of the blood, a rise of inorganic phosphorus. In cases in which the disease has been seen in the early paroxysmal stage, the remarkable fact was observed that under the administration of alkaline salts the inorganic phosphorus content of the blood may be elevated so quickly that the figure obtained before treatment is started may be doubled within one week. Thus, a reading of 2.6 mg. changes to 5.5 and again from 1.7 mg. to 4.3.

This change in the characteristic chemical values has been accompanied by pronounced clinical improvement, with remarkable and rapid amelioration of the distressing symptoms, so that vomiting would cease, on an average, in from four to five days and whooping in from eight to ten days, with occasional exceptions. The patient's general appearance showed corresponding improvement, and there was a gain in weight.[10]

In a small number of cases in which we had the opportunity of starting treatment in the late catarrhal stage, the disease was aborted before typical paroxysms were established, and this naturally brings up the thought of the possible prophylactic value of alkalis perhaps in conjunction with vaccine. In patients treated in the early and middle paroxysmal stage, the disease was quickly cured. It may be said, and this is a significant fact, that the cure bears no relation to the week of the disease when the treatment was begun, being as effective if not more so in the cases treated early as those treated late (table 2). We have not considered it advisable to use the treatment in bronchopneumonia complications, and instead have employed the mercury quartz lamp with good results. Our moderate and severe cases were treated by various combinations of alkaline powders—sodium bicarbonate, calcium carbonate and magnesium oxide. Mild cases were untreated. The alkalis used were selected mostly from an empiric standpoint, the original basis being the clinical effect of Sippy treatment for gastric ulcer in a patient[11] with severe pertussis and an ulcer of the stomach. Before the chemical study, the calcium was continued to conform to the possibility that the convulsions so frequent in pertussis might be similar to those of tetany and hence connected with a lowered calcium content of the blood. The results of our blood chemical study appear to be entirely against this assumption, and we feel it would probably be sufficient in treatment to use only sodium bicarbonate in adequate doses, in order to restore the acid base balance to normal. In many cases showing gastric intolerance, lime water may also be given with the feedings with benefit and if, as in neglected cases of severe pertussis, starvation has complicated the condition, glucose may be used in conjunction with the bicarbonate.[12]

[9] De Wesselow, O. L. V.: The Chemistry of the Blood in Clinical Medicine, p. 52.

[10] In routine treatment, it has been customary, at first, to start therapy by the administration of sodium bicarbonate in 30 grain (2 Gm.) dosage every half to one hour until from four to five doses have been given. Then the administration is begun of alkaline powders, mentioned in the previous paper, containing magnesium oxide, 15 grains (1 Gm.), with sodium bicarbonate, 15 grains, and calcium carbonate, 15 grains, with sodium bicarbonate, 15 grains, alternately each, three times daily given in milk, the powders being mixed with an equal amount of sugar and 1 drachm of milk (warm) and half a cup of milk added.

While the treatment proposed is, strictly speaking, apparently symptomatic, in that by adjusting an acid base unbalance it brings about changes in the organism which permit the return to a normal state, yet it probably is very intimately connected with the mechanism by which the termination of the vicious cycle accompanying the infection is brought about.

SUMMARY

A total of 682 blood chemical analyses performed in cases of pertussis have given the following results:

1. There is a diminution of the total inorganic phosphorus associated with a lowering of the hydrogen ion concentration of the blood, while the plasma bicarbonate remains within normal limits.

2. These changes occur early in the disease, appearing in the case of the inorganic phosphorus in the catarrhal stage.

3. Both alterations are well developed, especially the change in phosphorus, during the first few weeks of the paroxysms, and show a certain degree of parallelism in their course which signifies a close interrelation.

4. In moderate and severe cases treated with alkalis, the inorganic phosphorus rises steadily from the third week, while in untreated cases of the mild type, the rise does not begin until the sixth week. The same is true in a less decided way of a p_H value before, as compared to those during and after, treatment.

5. The diminution of inorganic phosphorus bears no relation to age, but only to the stage of the disease, and for reasons mentioned in the text has no underlying rachitic basis.

6. The calcium content, while exhibiting slight mobility, as the result, possibly, of shifting of calcium in connection with the characteristic phosphorus and p_H alterations, has no constant alterations of a distinct type.

7. These changes indicate an acidosis of an uncompensated type (type 6, Van Slyke), which has as a cause the accumulation or increased concentration of free carbon dioxide in the blood. This laboratory observation is easily correlated with several of the symptoms so prominent in pertussis—the paroxysms, the vomiting, parenchymatous emphysema and convulsions.

8. The vomiting of the disease may be a compensatory mechanism adopted by the body to eliminate acid in an attempt to maintain a normal acid base balance.

9. This contention of an uncompensated acidosis is further substantiated by the effects on the disease of alkali therapy.

10. Alkalis administered early appear usually to abort the disease, and associated with the cure is a rapid rise of inorganic phosphorus and a change in p_H of the blood, while, if given late, cure supervenes in a relatively short period.

CONCLUSIONS

There occurs in pertussis an uncompensated acidosis, which is intimately connected with the pathogenesis of the paroxysms.

If the acid base unbalance is corrected, the clinical symptoms are quickly ameliorated, and the organism returns to normal.

USE OF IODIZED OIL IN DIAGNOSIS AND TREATMENT OF BRONCHIAL AFFECTIONS

STUART PRITCHARD, M.D.
BRUCE WHYTE, M.D.
AND
J. K. M. GORDON, M.D.
BATTLE CREEK, MICH.

Iodized oil is used as an opaque medium in the roentgenographic study of body cavities. It was first employed by Sicard and Forestier in 1921 as an aid in locating and demonstrating obstructions of the spinal canal, and later was used successfully by the originators in exploring dilatations, fistulous tracts and cavities of the bronchial tree and the pulmonary tissues.

Since October, 1924, we have employed iodized oil in the form of bronchial injections as a diagnostic and therapeutic agent. This article is based on the results of this study and also the writings of Sicard and Forestier, Sergent and Cottenot, Nigoul-Foussal, Ballon, Archibald and others.

The iodized oil we have employed is the chemical compound of 40 per cent metallic iodine with oil of poppy seeds described and used by Forestier. The oil and iodine are so closely combined that the ordinary starch test fails to reveal free iodine.

Iodized oil is of clear amber color, is neutral in reaction, has a specific gravity of 1.350, and is insoluble in water or alcohol. The iodine may be liberated by the alkaline carbonates of the saliva and intestinal secretions, but is not affected by the gastric acidity. It becomes brown when exposed to the action of light, air, humidity and high temperature, because of the liberation of iodine. The high iodine content of the compound renders it opaque to the roentgen rays. The value of the oil as a diagnostic agent is due to its resistance to the roentgen ray and to its tolerance by the bronchial mucous membrane. The therapeutic advantages are due to the slow rate of absorption of the contained iodine without harmful effect on the patient. Iodism does not occur unless the oil is swallowed and subjected to the action of the intestinal secretions. The slow liberation of iodine prevents the danger of pulmonary congestion, which sometimes follows the use of iodides. It must not be used, however, when brown, on account of the caustic effect of free iodine.

There are four methods of introducing iodized oil into the bronchial tree: namely, the supraglottic, the transglottic, the subglottic and the bronchoscopic. In the first and second procedures, a curved cannula is used. In the subglottic method, a hollow curved needle is passed through the cricothyroid membrane into the trachea, while in the fourth the oil is introduced through the bronchoscope.

---

[11] Regan, J. C.: Report of a Case of Pertussis Complicating a Gastric Ulcer, M. J. & Record **120**: 381 (Oct. 15) 1924.

[12] A comparative study is now being made of the effect of irradiation by the mercury quartz lamp on the chemical change of the blood and on the clinical course of the disease.

The following general principles should be observed in all methods:

1. The use of discolored oil should be avoided.
2. Warm oil should be used, as it flows more freely and lessens the tendency toward cough.
3. Solutions for anesthesia should be warmed.
4. Roentgenographic exposures should be made as soon after injection as possible, and cough should be prevented by any unnecessary movements of the patient.

METHODS OF INTRODUCTION

Supraglottic.—In some patients the injection can be made without local anesthesia, but a better procedure is to swab the pharynx, soft palate (velum) and the base of the tongue with a 10 per cent cocaine solution. After an interval of three minutes, 1 cc. of warmed 1 per cent cocaine solution should be dropped into the glottis with the aid of a laryngeal mirror, syringe and curved cannula. Five minutes later the injection can be made. The patient sits facing the operator and slightly inclined toward the side to be injected, and is instructed to pull the tongue forward and breathe normally throughout this stage of the operation. A 20 cc. syringe filled with warmed iodized oil is firmly attached to a 6 inch cannula having its distal end curved to a right angle or less. With the aid of a laryngeal mirror, the tip of the cannula is introduced behind the base of the tongue held over the glottis, and the oil is slowly expelled from the syringe into the larynx. We have found that it is best to give no instructions to the patient regarding the manner of breathing, except in case of threatened cough, when a deep inspiration is advised.

Transglottic.—This method of injection is made with the tip of the cannula passed through the glottis into the trachea. The pharynx, velum and base of the tongue are anesthetized as in the supraglottic method, but for the larynx and trachea the quantity of 1 per cent cocaine is increased to 1 to 3 cc., on account of the deeper degree of anesthesia required.

Subglottic.—In this method, devised by Rosenthal, any difficulty in passing the larynx is avoided, and the oil is injected directly into the trachea. After anesthesia of the skin and subjacent tissue, a hollow curved needle attached to a metal guard is pushed through the cricothyroid membrane and into the lumen of the trachea. The position of the needle should be verified by attaching a syringe and aspirating, the withdrawal of air or mucus showing the needle to be in the trachea. From 1 to 2 cc. of warmed 1 per cent cocaine solution is then slowly injected through the needle, in order to anesthetize the mucosa of the trachea and bronchi of the desired area. The patient may cough for a short time. After from three to five minutes the iodized oil should be injected by means of a metal syringe firmly connected with the needle by a piece of strong rubber tubing. The tubing allows a certain motility of the syringe and must be strong to withstand the pressure necessary to force the oil through the needle.

POSITION OF PATIENT

The patient's position during injection is important as the distribution of the oil is determined by gravitation and the aspirating power of the lung. If one observes the progress of the oil on a fluoroscopic screen during injection, the greater portion may be seen to follow the most dependent bronchial trunks. For this reason the inferior lobes are most easily injected with the patient sitting. The oil is directed to the right or left bronchus by inclining the patient slightly in a corresponding direction during the injection. The middle and upper lobes can be injected only when the patient is lying, and with this position the supraglottic method is still effective, but the transglottic, the subglottic and the bronchoscopic may be used. To fill the apical bronchi, the patient should be placed on a tilting table with the desired side downward. A few seconds after the injection, the head of the table is lowered for a minute to permit the oil to flow into the upper lobe.

A useful exploration requires from 10 to 20 cc. of oil, and in the presence of large bronchial dilatations the lung will accept 40 cc. without evidence of distress. When injecting more than 20 cc. of oil, the transglottic, subglottic or bronchoscopic method is preferable.

COMMENT ON METHODS

In the application of any method, the patient should be told what is being attempted, and assurance given. In this way cooperation is obtained, time is saved, less anesthesia is used, and better results are accomplished.

The supraglottic method without anesthesia will seldom be successful with patients who are apprehensive or in whom the larynx and trachea are irritable from previous cough of long standing. Even with anesthesia, it is rejected by Forestier [1] as being rarely satisfactory. On the other hand, it is upheld by Claisse and Caussade.[2] In our experience, the supraglottic method with local anesthesia has been successful in the great majority of cases, and in the absence of unusual laryngeal irritability it is always tried first. The method, however, is more satisfactory in the injection of areas lying at or below the level of the lung roots, as the oil follows the path of least resistance.

Prior to the bronchial injection, the patient should have a physical examination of the chest and a roentgenologic study. When the examination is repeated after the injection, considerable information may be obtained regarding bronchial irregularities, the size, shape and position of the trachea, and a detailed knowledge of the contents of the lung root zone not otherwise revealed by any other diagnostic procedure. The roentgen-ray study should include oblique stereoroentgenograms in addition to the ordinary postero-anterior exposures. The trachea and its bifurcation are thereby clearly outlined, and images which otherwise would remain obscured by the cardiac and diaphragmatic densities are definitely exposed.

It is necessary to make the postoperative roentgen-ray study immediately following the injection, with as little disturbance of the patient as possible, for the reason that with the return of the cough reflex the larger bronchi may become partially emptied and valuable information be lost. Hence, in a patient showing unusual irritability of the trachea, it may be necessary to abandon the technic and make both the injection and the exposures on the roentgen-ray table.

The practitioner intending to use iodized oil in the diagnosis of pathologic conditions of the lungs should first practice injections in normal subjects, and so learn to recognize the shadows characteristic of all parts of the uninjured bronchial tree.

[1] Forestier, Jacques: Iodized Oil in Radiologic Practice, Paris méd. 1: 377 (April 26) 1924.

[2] Claisse, P., and Serrand, J.: Bull. et mém. Soc. méd. d. hôp. de Paris 46: 579 (April 7) 1922.

In the normal (fig. 1), the trachea and the large bronchi are shown in outline by the oil, which clings to their walls, but the smaller bronchi appear as continuous solid lines, which diminish in width as they approach the thoracic wall. Surrounding the bronchi, the filled alveoli are represented by a coarse stippling. After the patient has coughed, the hitherto unbroken line of the bronchial shadow becomes interrupted, but the alveolar shadows remain. This broken bronchial line can also be caused by the use of an insufficient quantity of oil. The alveolar shadows remain unchanged for about twenty-four hours and then gradually disappear during the ensuing ten days. Forestier [3] says that the urinary elimination of iodine passes its maximum after the third day but persists to the amount of several milligrams daily, as long as there are pulmonary shadows.

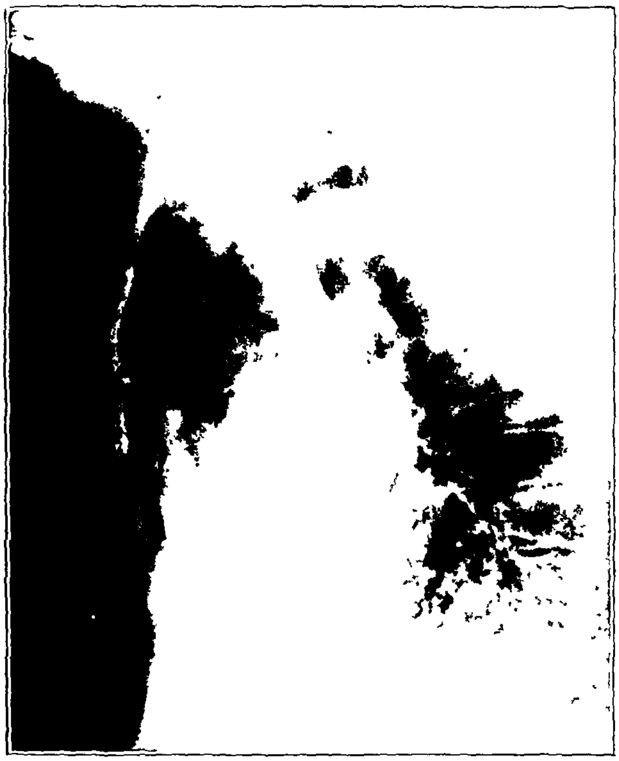

Fig 1.—Outline of the trachea and its relationship to the arch of the aorta.

PATHOLOGIC PICTURE

The sharply defined outline of the trachea and its bifurcating branches enables one easily to recognize the exact site of conditions such as deviation or compression. It is unwise to dismiss the possibility of an anteroposterior compression of the trachea without the study of films taken in the oblique or lateral position (fig. 1).

Iodized oil, however, finds its greatest usefulness in the visualizing of bronchial dilatations and particularly in those earlier cases wherein cough is the chief or only symptom, and both physical examination and the roentgen ray fail to locate the focus. After injection, these early dilatations are shown as small, pouch-like shadows. Those of longer standing (more advanced) may be cylindric or may resemble a hanging bunch of grapes (fig. 2), drops of tar or even the fingers of a glove, as described by Sergent and Cottenot.[4] These abnormal shadows stand out in excellent contrast with the regular and more delicate outlines of the surrounding normal area.

The presence of fragmented bronchial lines in films made before the patient begins to cough may be considered as evidence of the presence of abnormal bronchial secretions, provided one can exclude an insufficient quantity of oil as a cause.

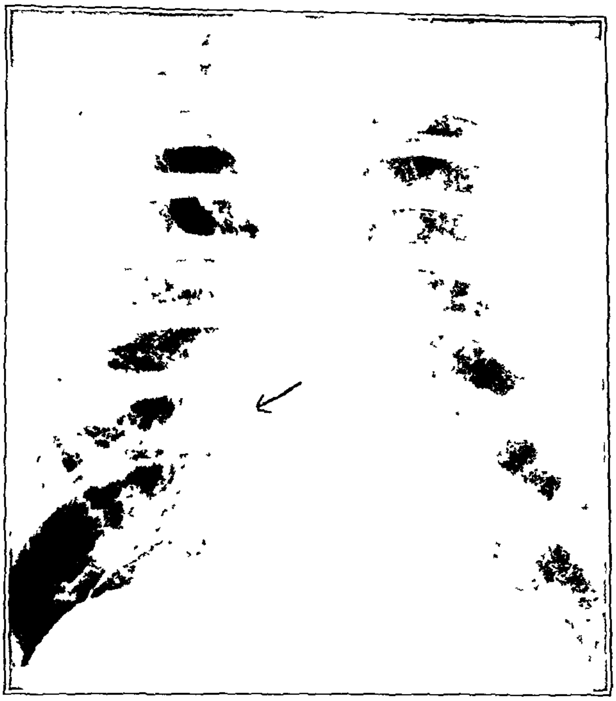

Fig 2.—"Bunch of grapes" bronchiectatic area, revealed by the injection of iodized oil.

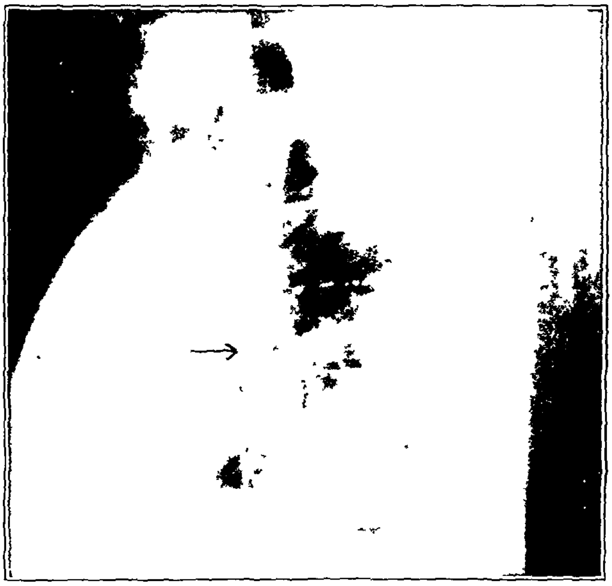

Fig 3.—A well visualized lung abscess in the left thorax caused by a long embedded foreign body, which was recently removed from the left bronchus.

---

[3] Sicard, J. A., and Forestier, Jacques: J. de méd. franc. Paris **13**: 3-9, 1924.

[4] Sergent, Emile, and Cottenot, P.: Presse méd. **33**: 500 (April 18) 1925.

It is evident, then, that any pulmonary cavity can be shown roentgenographically if its bronchial outlet allows the inflow of iodized oil. We have not found occasion for injecting a tuberculous pulmonary cavity, but we have succeeded in locating the cavity of a foreign body abscess which, on the regular film, remained hidden (fig. 3.) This fact suggests that this procedure with serial oblique films might be a valuable aid in thoracic surgery. In the exploration of thoracic fistulas, the fluidity of iodized oil renders it superior to bismuth paste. Archibald[5] has drawn attention to the value of this oil in demonstrating the persistence of tuberculous cavities and bronchial dilatations after thoracoplastic operations.

We find the injection of iodized oil of great value in patients presenting symptoms of persistent cough, occasional fever and expectoration free from acid fast bacilli. These patients complain of exhaustion and are underweight. Their cases are frequently diagnosed as tuberculosis, and the physical examination, laboratory findings, and roentgenologic study give no definite information as to etiology. The following cases will illustrate the point:

M. C, a man, aged 36, 5 feet 6 inches (168 cm.) tall, weighing 131 pounds (59 Kg.), with an average weight of 140 pounds (64 Kg.), was pale, was nervous, and tired easily. A chronic cough persisted for eight years, following influenza. The expectoration was scanty and revealed no acid fast bacilli or elastic tissue. At times the cough was increased in severity, and some slight degree of fever was present. The patient complained of a heavy dull pain under the middle of the sternum. He had been told that he had tuberculosis. After a careful physical examination, laboratory test and roentgen-ray study of the chest, no abnormalities were found, except rhonchi over the right lung root zone in the back. Iodized oil was injected into the right root and base, and a distinct bronchiectatic dilatation (fig. 2) was shown at the edge of the right lung root density. The patient was given an injection of 10 cc., once a week for six weeks and, eight months later, he reported that since then he had had no cough or expectoration and felt well. The supraglottic method was used, and no local anesthesia was administered after the first injection.

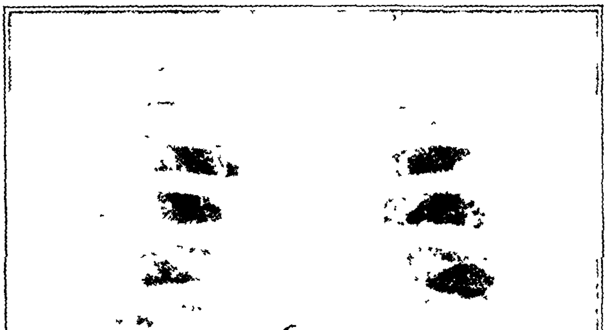

Fig 4.—Large irregular bronchiectasis, not discovered until after the injection of iodized oil.

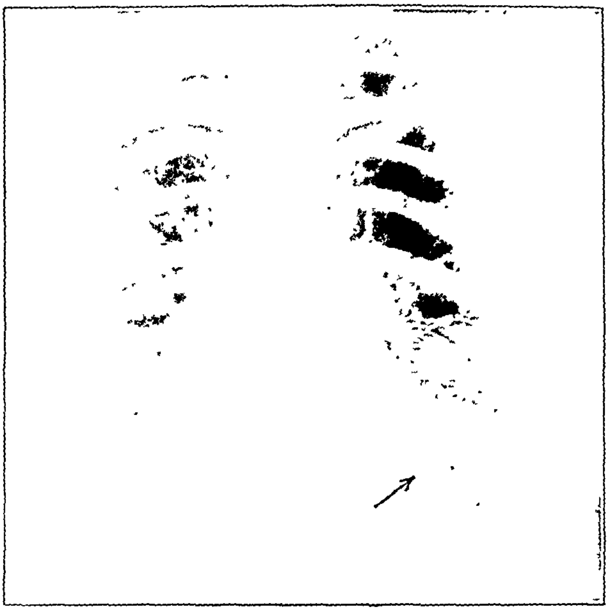

Fig 5.—Cylindric type of bronchiectasis, revealed after the introduction of 15 cc. of iodized oil into the left lower bronchial tree.

M K., a woman, aged 52, had had chronic cough, associated with about 10 to 20 cc. of purulent but odorless expectoration daily, following an acute bronchitis five years previously. No acid fast bacilli or elastic tissue was found (pig inoculation). There was no clubbing of the fingers, no loss of weight or history of fever. The patient complained of fatigue and of the annoying cough and expectoration. Physical examination and roentgenologic studies of the chest showed no abnormalities, except that the right root shadows were somewhat prominent. The nose and throat were normal. Twenty cc. of iodized oil was injected into the right lung root zone by the supraglottic method. A very distinct irregular bronchiectatic dilatation (fig 4) was revealed in the inner right lung root zone, over which grouped râles were found, the result of the retention of the oil. This area was in all probability the seat of the bronchial affection; lack of drainage caused a persistent multiplication and accumulation of bacteria. Fourteen injections of 12 cc. of iodized oil were given this patient at intervals of not less than five days, the object in treatment being completely to fill the small bronchial dilatations. Five months after the last injection, the patient reported much less expectoration and only a slight cough.

M. P., a woman, aged 36, had had a cough since she was 18 years of age, following a severe attack of acute bronchitis. For the past twelve years, the cough had been loose, productive and became worse on lying down. The sputum was yellow, offensive and from 30 to 40 cc. in quantity daily; no acid fast bacilli or elastic tissue was found (pig inoculation). The fingers were definitely clubbed. The nutrition was good. There were occasional attacks of fever. For the past three years, the condition had been growing worse. Scattered rhonchi were heard on physical examination of the chest. Anterior and oblique stereoroentgenograms showed no abnormal densities. The nose and throat were normal. Fifteen cc. of oil was injected into the right lung root and descending bronchial tree, with no signs of dilatation. Later, the left root and descending bronchial areas were injected, and a number of cylindric bronchial dilatations were found (fig. 5). Sixteen injections of 10 cc. each were given over a period of eleven weeks. Four months after treatment, the patient showed a marked improvement. The sputum had greatly decreased in amount and was odorless. A slight cough remained, but the patient reported that she has never felt so well in years.

---

[5] Archibald, Edward: Canad. M. A. J. 15:1000 (Oct.) 1925.

CONCLUSIONS

1. By the injections of iodized oil into the bronchial tree, small bronchiectatic dilatations in and around the roots of the lungs and cylindric fusiform enlargements of the descending branches may be revealed in many cases of chronic cough, which a previous exhaustive examination of the chest failed to show.
2. The entire bronchial tree cannot be visualized at one injection. Small sections should be injected at intervals until any abnormality is discovered or the entire field is studied.
3. The nose and throat should be studied in all cases. Bronchiectatic cavities occur as the result of chronic upper respiratory infections, and may continue to cause cough after the tonsils are removed or the sinuses drained.
4. In the majority of cases, we feel that the supraglottic method of injecting the lung roots and descending branches of the bronchial tree takes less time, less anesthesia, is less worry to the patient and gives results quite as satisfactory as other methods.
5. It is not necessary to use extensive local anesthesia in the majority of cases.
6. In more than 600 bronchial injections of iodized oil, we have seen no ill effects in our patients. No cases of iodism occurred.

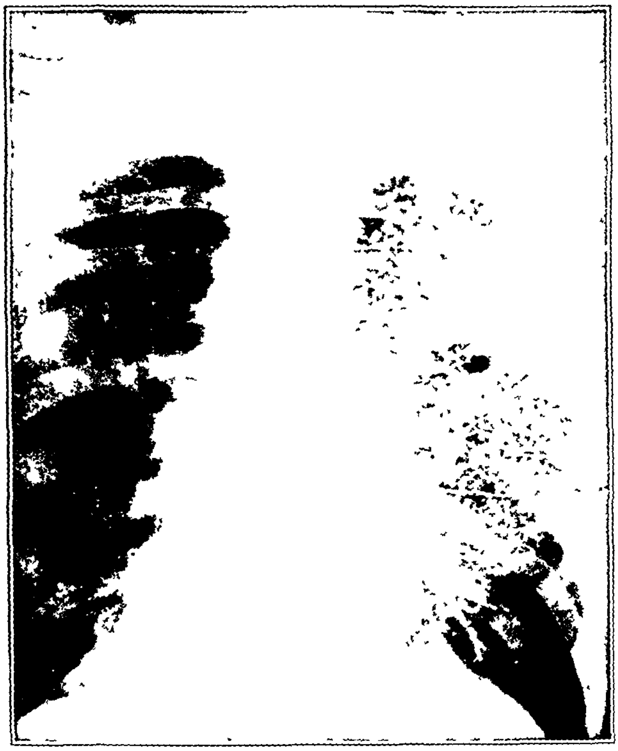

Fig 6.—Result of an excessive amount of iodized oil obliterating the bronchial markings. Injection by the subglottic method.

7. The technic is not difficult. It requires no special training.
8. Negative results of an injection are no diagnostic proof that bronchiectatic dilatations do not exist.
9. The therapeutic use of iodine is not new but this compound of iodized oil is a new combination and, as a result of the slow liberation of the iodine in the bronchial tree, acts as an ideal treatment in chronic affections of the lower respiratory tract.

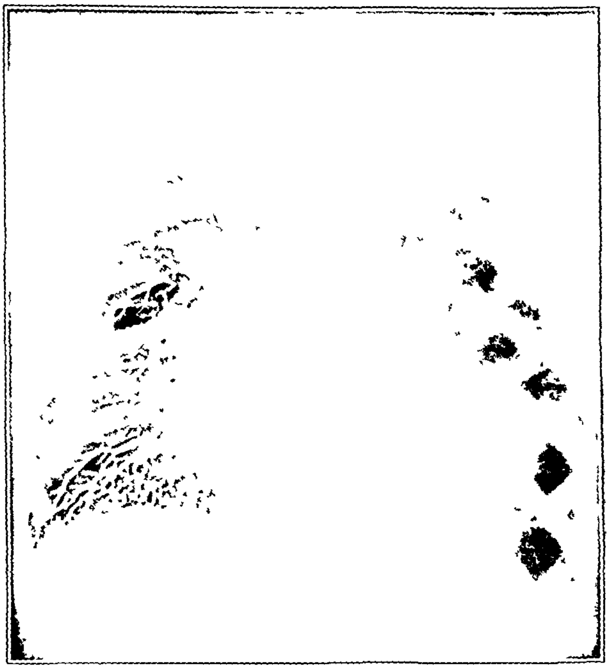

Fig 7.—An evenly distributed injection of 25 cc of iodized oil in the right bronchial tree, by the transglottic method duplicated later by supraglottic method.

10. In acute affections or pulmonary tuberculosis, we hesitate to inject iodized oil for either diagnostic or therapeutic purposes.

OMENTOPEXY IN CIRRHOSIS OF THE LIVER

REPORT OF CASE

FREDERICK W. LESTER, M.D.
SENECA FALLS, N. Y.

Cases of atrophic cirrhosis of the liver are still sufficiently common to attract the surgeon's attention for the relief of the ascites. These patients with various complicated lesions, and with a shaky cardiovasculorenal tripod, do not make desirable operative risks, and careful judgment is advisable in their selection.

The temptation to relieve the accumulations of fluid in the abdomen by repeated paracentesis is one to which the physician frequently succumbs. That such treatment is without substantial avail has long been known.

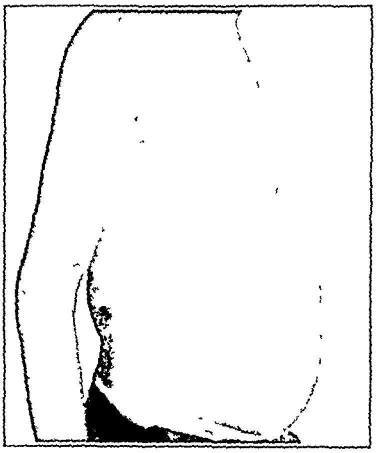
Binnie, quoting Wynter, says, "The price paid for the relief of the distention is the sacrifice of so much nutrient fluid," and Osler confirms this, stating that "the average duration of life in atrophic cirrhosis, after the commencement of tapping, is about fourteen weeks."

Omentopexy, or epiplopexy, known as Talma's operation, also termed Morrison's operation and Narath's operation, is a surgical procedure devised on a truly scientific basis, with the object of attempting to restore, at a single stroke, the normal function in an organ (the liver) crippled by disease. That this restoration actually does take place as the result of omentopexy, even though it is deferred for a period of weeks, there can be no doubt.

In the chronic ascites that results from the interference with the portal blood circulation in advanced hepatic cirrhosis, omentopexy, by using the omentum in a variety of methods, as a carrier or go-between, attempts to effect an anastomosis between the visceral blood vessels and the peripheral circulation with the result, if successful, of not only relieving the ascites permanently, but also benefiting indirectly the other chief function of the liver, that of bile production.

Keen [1] mentions some of the older writers advocating surgical methods in dealing with ascites; for instance, Litthauer, Comer and Pinches, Sir Spencer Wells, Hearn and Péan. Their writings, with those of Talma, Morrison, Rubin and Narath, make up the rather meager literature of a generation ago. They are entitled to all honor as being the originators of omentopexy and the pioneers in the surgery of the omentum.

A search of the literature of the last few years finds numerous references to the surgery of the liver and omentum, but rather scant mention of the use of omentopexy in hepatic cirrhosis. Bremer,[2] Weber,[3] Loeper and Turpin,[4] Fiessinger and Brodin,[5] Tagliavacche,[6] Sternberg,[7] and Rowntree,[8] during the last two years, have described some of the phenomena attending the presence of ascites and the various methods of its treatment, both medical and surgical, including omentopexy. In these instructive papers may be found reports of the successful use of omentopexy in patients from the age of 16 upward. General agreement seems to place the rate of mortality for omentopexy at from 5 to 20 per cent. No long series of cases were reported.



Appearance of abdomen after omentopexy, showing "omental hernia" in epigastric region.

In the case described below, thirty-two months after operation, the result is so satisfactory that I feel greatly interested in this method of treatment. It may be of interest to others.

REPORT OF CASE

J. M., a white man, aged 67, had suffered for more than a year, with "stomach trouble," including nausea and indigestion, which began gradually. The family history was unimportant and the personal history presented nothing of special note, except that the patient had used strong chewing and smoking tobacco for many years and whisky, sometimes a dozen drinks a day, for the past two or three years. April 9, 1923, he had hemorrhoids and hydrocele of the right tunica vaginalis testis; there was an accumulation of fluid in the abdomen. Liver dulness was present, and the liver was palpable 2 inches (5 cm.) below the costal margin. The spleen was not palpable but showed an increased area of dulness. The heart presented a high pitched systolic murmur at the apex, with increase in size of the left ventricle. Rectal examination showed a prostate of normal size, with no tenderness. The hydrocele was tapped, and 400 cc. of fluid evacuated; one hemorrhoid was removed by clamp and cautery. May 15, the abdomen was full of fluid, distended and large.

Laboratory tests revealed that the specific gravity of the urine was 1.020, with a trace of albumin and a few light granular casts, but no sugar. The Wassermann reaction was negative to both antigens. Tallqvist's test gave 65 per cent of hemoglobin. No tuberculosis foci were found in the general examination. The stools were light brown.

The phenolsulphonphthalein test showed considerable reduction in the excretion of the dye, about 28 per cent being excreted in the first two hours.

The patient was admitted to the Memorial Hospital, Waterloo, N. Y., May 15, 1923. The working diagnosis was ascites from cirrhosis of the liver, chronic interstitial nephritis and mitral regurgitation, with hypertrophy of the left ventricle of the heart.

Operation was done, May 16, 1923, the Narath[9] technic being used. After the abdomen was opened through the right rectus muscle above the umbilicus, and all the fluid that could be secured, about 6,000 cc., was evacuated and sponged away, the omentum was brought out of the incision; it was rather short, not over 4 or 5 inches (10 to 13 cm.) long and nonadherent. The liver was then palpated and a general visceral examination made. No special abnormalities were noticed, except that the liver was rather stiff and indented on its external surface at numerous points. A pocket was then made at the right side of the incision by raising the skin and superficial fascia. Into this pocket was inserted a portion of the omentum, about three fourths of the total bulk, which was securely fastened there by means of several chromic catgut sutures. The portion of omentum, thus brought outside the abdomen, was then fastened around its base to the edges of the opening in the peritoneum through which it came, and the abdomen closed in layers without drainage, four or five silkworm interrupted sutures being used through the skin and fascia as supporting sutures. The time of operation was forty-five minutes; ether was given by the drop method.

The patient's immediate postoperative condition showed no serious effects, a little yellow fluid being vomited.

May 17, the abdomen was tympanitic.

May 18, gas came freely through the rectal tip, and the abdomen was softer. The temperature was 99.6; the pulse was 96.

May 23, drainage from the wound began and amounted to about 300 or 400 cc. daily of clear serous fluid.

May 26, the serous drainage changed to a bright green, and the amount became very much less.

May 28, drainage had stopped completely.

May 30, the supporting sutures were removed.

June 2, the patient was sent to his home.

June 9, fluid began to reaccumulate in the abdomen.

June 16, 4,000 cc. of fluid was obtained by paracentesis.

June 28, the fluid began to return.

July 9, the fluid was present but not increasing.

July 23, it was receding.

August 1, the fluid was completely gone.

Jan. 1, 1926, examination showed an abdomen with an "omental hernia" in the epigastric region, which caused the patient no discomfort. He is able to work from six to eight hours daily at his trade. The right hydrocele requires tapping about once in six months. The liver showed no increase in size. Hemorrhoids were not present. The appetite and digestion were good.

COMMENT

1. The stormy convalescence, with no evidence of circulatory balance in the liver for from six to eight weeks, indicated that the anastomosis was, for that length of time, ineffective.
2. There were late good and permanent effects of the anastomosis.
3. No injurious effects resulted from diverting so large a part of the omentum from its usual location.

PAROXYSMAL TACHYCARDIA ASSOCIATED WITH FOCAL MYOCARDITIS *

RALPH H. MAJOR, M.D.
AND
H. R. WAHL, M.D.
KANSAS CITY, KAN.

Tachycardia of ventricular origin is an uncommon condition, and the number of reported cases is comparatively small. Butterfield and Hunt,[1] Cohn,[2] Gallavardin,[3] Hart,[4] Lewis,[5] Marvin and White,[6] Robinson and Herrmann,[7] Scott,[8] Vaughan,[9] and Willius[10] have reported examples of such tachycardias. Scott, who reviewed the subject in 1922, doubted whether certain cases reported as ventricular tachycardia were correctly diagnosed, and states that, of twenty cases reported up to that time, the evidence is not convincing in more than half. Wolferth and McMillan,[11] in 1923, collected reports of twenty-two cases, which they regarded as examples of true ventricular paroxysmal tachycardia.

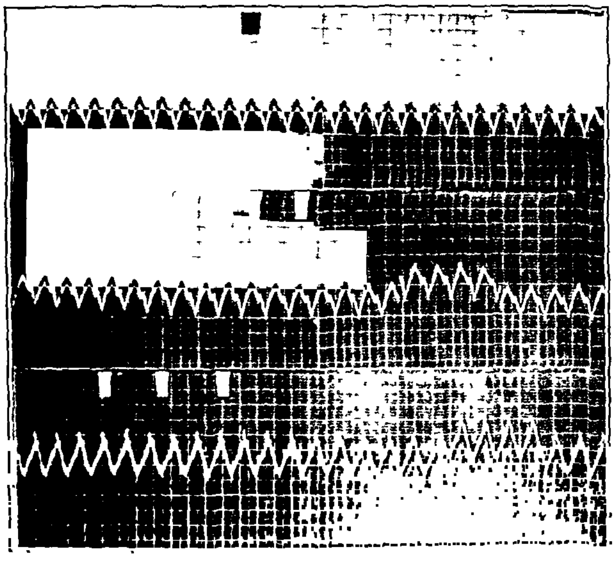

Fig. 1.—Condition, May 28, 1925: type of electrocardiogram usually associated with ventricular paroxysmal tachycardia

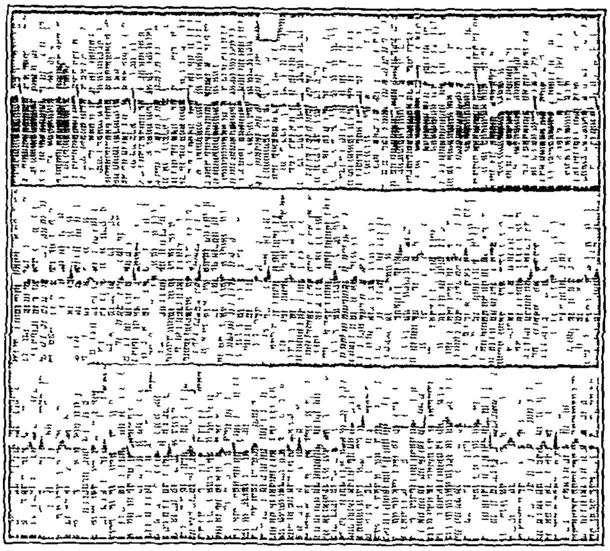

Fig 2—Condition, June 15, 1925: inversion of T wave in the first lead and distinct notching of R wave in the second lead.

Lewis has pointed out that the ventricular type of electrocardiogram is not necessarily due to paroxysmal tachycardia of ventricular origin, since a similar picture is produced when the excitation wave takes an abnormal course in the ventricle. One case of Marvin and White's probably belongs to this category, since it gave electrocardiograms of the ventricular type, although it was proved to be a tachycardia of auricular origin.

A patient whom we have recently studied showed a paroxysmal tachycardia of considerable interest from the standpoint of its causation and the type of electrocardiogram shown.

REPORT OF CASE

A man, aged 25, who had had two attacks of rapid beating of the heart since the age of 12, the last attack occurring six years previously, had suffered from infected tonsils for several years, and during the past eighteen months had known of the presence of several badly infected teeth.

The patient was admitted to the Bell Memorial Hospital, May 28, 1925, suffering from an attack of paroxysmal tachycardia, which came on without warning. Electrocardiographic tracings made during this attack are shown in figure 1. These tracings are of the type that is usually associated with a tachycardia of ventricular origin, although, as mentioned, the same type is occasionally encountered in certain tachycardias of auricular origin. We were unfortunate in not obtaining an electrocardiogram of either the beginning or the ending of the attack, which is a necessary criterion for establishing the positive diagnosis of ventricular paroxysmal tachycardia. The pulse rate varied from 200 to 240 per minute. The patient was given two-thirds grain (0.04 Gm.) of pantopium hydrochloricum (pantopon) by mouth and 0.025 mg. of ouabain hypodermically. Three hours after this medication, the pulse rate suddenly fell to 100, and the patient was more comfortable. The next morning the pulse was 88, and he was dismissed from the hospital. June 15, 1925, electrocardiographic tracings were taken, which showed slight notching of the R wave in both the first and second leads and inversion of the T wave in the third lead. There were no extrasystoles seen (fig. 2).

At the time of discharge from the hospital, the patient was advised to have some dental work carried out, and during the summer several infected teeth were removed. The culture from these teeth showed an anhemolytic streptococcus, which was studied by Dr. R. L. Haden, who found that it showed a tendency to localize in the myocardium when injected into rabbits. The patient had a recurrence of tachycardia, Sept. 23, 1925, and at that time received 0.025 mg. of ouabain hypodermically, the injection being followed by a cessation of the attack. Five hours later another attack came on, and the patient died within three minutes of its onset. He was observed in this attack by a physician, who stated that at the time of death there was a marked quivering over the precordium. We did not see the patient during this attack, but the description was suggestive of death from ventricular fibrillation.

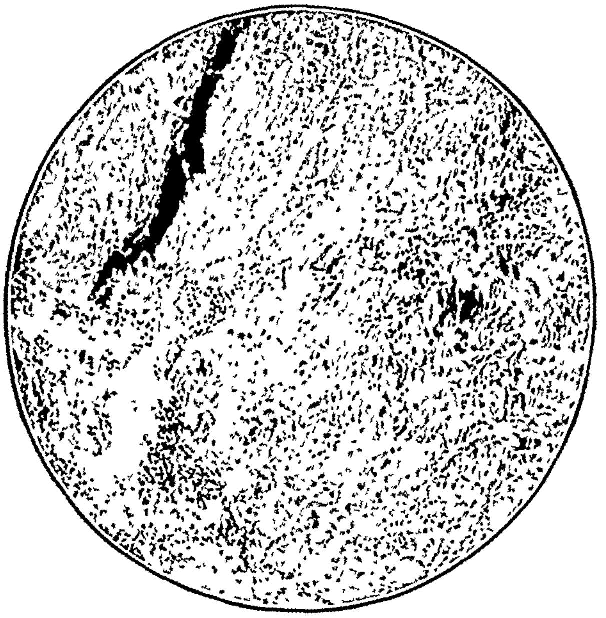

Fig 3.—A section through the left auricle, showing numerous collections of polymorphonuclear leukocytes and lymphocytes, slightly reduced from a photomicrograph with a magnification of 120 diameters.

The necropsy was limited to an examination of the heart. It weighed 335 Gm., was very flabby, and on the anterior surface there were several opaque patches, the evidence of old chronic pericarditis. The heart valves were normal in appearance; the base of the aorta showed numerous small yellow atheromatous plaques, measuring from 2 to 4 mm. in diameter. The coronary arteries showed grossly no sclerosis. A large number of sections were made through the walls of both auricles, the interventricular septum, and both ventricles. The sections through the left auricle showed areas containing foci of polymorphonuclear leukocytes, with collections of mononuclear cells and eosinophils (fig. 3). A similar picture was found in the sections through the right auricle, the left ventricle and the interventricular septum, including the bundle of His. There was a large amount of degeneration of the cardiac muscle fibers in all sections. One section through the left ventricle showed thickening and hyaline degeneration of the walls of the blood vessels and numerous patches of fibrosis in the myocardium. A section through the left coronary artery showed thickening of the intima, with vacuolar change in some of the cells. There were also some diffuse accumulations of mononuclear and polymorphonuclear leukocytes involving the inner portion of the media and intima. A section through the left coronary vein showed a small branch filled with pus cells.

The anatomic diagnosis was: acute and chronic myocarditis of the focal type; parenchymatous degeneration of the myocardium; aortic intimitis; early focal arteritis of the coronary arteries, and chronic pericarditis.

The evidence in this case favors the diagnosis of ventricular tachycardia, although this cannot be positively asserted. The association of the focal infection of the tonsils and teeth with foci of infection in the myocardium is very significant. We are probably dealing here with a tachycardia due to myocarditis, which was the result of the streptococcic focal infection from which the patient suffered. It is of extreme interest that the patient showed a definite early arteritis of the coronary arteries, apparently due to the same cause. He had atheromatous plaques on the aorta, which were far more numerous than would be expected in a man of his age. These findings bring up the question of the relationship between focal infection and arterial lesions, which have not been regarded by many observers as being entirely degenerative in their origin.

Very few necropsy reports on patients suffering from paroxysmal ventricular tachycardia have been reported. Robinson and Herrmann describe a thrombosis of the anterior descending branch of the left coronary artery in one of their cases, and Butterfield and Hunt found fibrosis of two thirds of the interventricular tissue in one patient at necropsy. Willius states that four of his patients gave definite histories of previous infection with the streptococcus group and that in one fatal case marked atheroma of the left coronary artery was found. In our patient we have, we feel, definite evidence of the rôle that streptococcic focal infection may play in cardiac and arterial changes.

Clinical Notes, Suggestions, and New Instruments

CUTIS VERTICIS GYRATA *

Raymond J. Sisson, M.D., Detroit

Cutis verticis gyrata is a skin condition of rare frequency characterized by hypertrophy and looseness of the skin, with a tendency to hang in folds. The literature referable to it is very meager. I report this case because of its infrequency and of a glandular derangement, not previously observed, which is present.

CLINICAL HISTORY

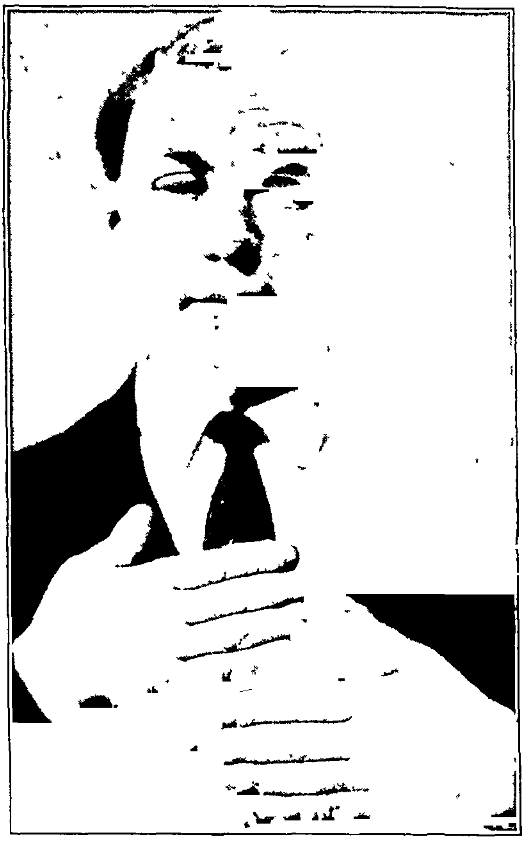
M. C., a man, aged 29, with a dark complexion, seen, Nov. 25, 1924, complained of thickness of the upper eyelids. Since childhood the fingers and toes had been large. An "eczema" of the scalp five years ago yielded promptly to treatment. The onset of the present illness occurred five years ago. The scalp was first affected and the condition gradually spread over the forehead and eyelids. The weight of the lids was so great that the patient had considerable difficulty working.

Vision in both eyes was 20/30. A marked mechanical ptosis with thickness of both upper lids was present. There was no other ocular pathologic change. The skin of the forehead and scalp was markedly thickened and thrown into transverse folds and furrows. Much oily secretion was present on the skin of the forehead and scalp. The hair was coarse and oily. There was typical enlargement of the terminal phalanges.

---

* From the Massachusetts Eye and Ear Infirmary

General medical examination revealed the presence of acromegaly. A roentgenogram showed a pituitary fossa of normal size and shape, and there was characteristic clubbing of the terminal phalanges. In addition, the outline of the lower end of the radius and ulna was somewhat irregular, suggesting periosteal proliferation. The tibia and fibula were considerably increased in width, and an increased density with irregularity of bone outline suggested periosteal proliferation. The clinical diagnosis was cutis verticis gyrata, acromegaly, and ptosis (mechanical).



Appearance of patient with cutis verticis gyrata, showing furrows of the forehead, ptosis and enlargement of the terminal phalanges, Nov. 25, 1925.

November 26, under local anesthesia, an elliptic strip, including conjunctiva and tarsus, was excised from the right upper lid for pathologic examination.

Six roentgen-ray treatments, one every two weeks, were given at the Massachusetts General Hospital, under the direction of Dr. C. G. Love of the skin department. There was definite relief from the oil, but no apparent change in the thickness of the lids. Further treatment was not advised. May 13, 1925, an elliptic piece of skin was excised from the left upper lid. The patient was last seen, June 2, 1925, at which time the condition was unchanged.

PATHOLOGIC EXAMINATION

The material examined consisted of one elliptic piece of tissue, including conjunctiva and tarsus, excised from the right upper lid, by Dr. F. H. Verhoeff. After formaldehyde fixation it was embedded in celloidin and sections were stained in hematoxylin and eosin. Dr. Verhoeff found chronic conjunctivitis with marked proliferation of palpebral conjunctiva with formation of glands. Many of the glands were distended with concretions. The tarsus was practically free from infiltration.

COMMENT

The name cutis verticis gyrata was chosen because the condition is characterized by furrows occurring in the skin over the crown and back of the head which suggest the appearance of gyri and sulci of the brain. The first clinical study of this condition was made by Jadassohn.[1] Unna[2] subsequently described it and gave it the name. All patients have been men who, with one exception, had dark complexions. Only a few cases have been reported, and none were associated with acromegaly.

Stelwagon[3] says: "The hypertrophic form of dermatolysis may be congenital or acquired, and vary in its limitation and in the region affected. All parts of the skin, including the follicles, glands and subcutaneous tissue, share in the hypertrophy. The follicles are enlarged and a tendency to increased pigmentation exists." Bogrow[4] thinks it is due to congenital tendency to furrows intensified by subsequent infection. The association of this case with acromegaly suggests a possible endocrine basis.

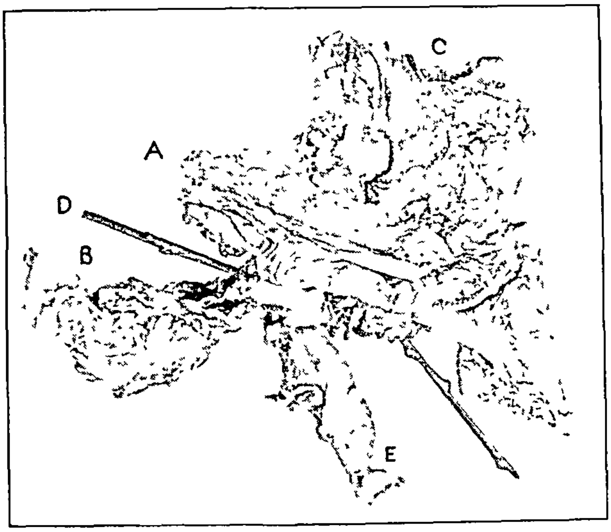
CANCER OF STOMACH *

JOHN WILLIAM SHUMAN, M D, LOS ANGELES
Senior Attending Physician, Los Angeles General Hospital

Seldom is the opportunity given to check up on one's colleagues as closely and accurately as this case affords. The case is worth while reporting because of the lesion, the radical operation performed seventeen years prior to death, and the ease with which all facts pertaining were assembled

A man, aged 52, admitted in May, 1925, complained of loss of weight as a result of inability to take and assimilate food. From then until his death, November 23, repeated and detailed examinations failed to diagnose more than gastric malignancy. His history stated that part of the stomach was cut away and a new opening made by Dr. William Mayo, sixteen years previously. The patient had fair health until eight months before coming to the hospital. The roentgenogram showed a functioning gastro-enterostomy; about one third of the stomach, the cardiac end, could be seen Hydrochloric acid was absent Occult blood was present in the constipated stool Anemia was so like the picture of pernicious anemia that several of the attending physicians diagnosed it as such The color index was 1.5. The patient died from inanition



Stomach at necropsy: *A*, pyloric end; *B*, blind pouch of duodenum, *C*, cardiac end; *D*, twig run through to show colon, *E*, pancreas

Necropsy by Dr. George B. Maner showed the upper half of the stomach converted into a firm nodular mass, which was tightly adherent to the anterior flange of the diaphragm and impossible to separate without tearing. The pylorus had been resected and a posterior gastrojejunostomy had been done, not recently. The stomach was funnel shaped, about 12 cm. long and 7 cm. wide at the top, the enterostomy opening being the tip. The closed end of the duodenum could be demonstrated, as shown in the accompanying illustration. There was no infiltration of the pancreas, colon, spleen, lymphatics and other viscera.

* From the Department of Internal Medicine, Los Angeles General Hospital.

The cause of death was extensive carcinoma of the cardiac end of the stomach.

A brief report, protocol and photograph sent by Dr. Mayo brought the following: ". . . The information you have given us is of value for our records. I am sorry to learn of his death, but it is gratifying at least to know that he has had sixteen years of life, following his operation here in 1908. This patient came to the Mayo Clinic, Oct. 19, 1908, and was operated on here, October 27, for a tumor, clinically malignant, of the pyloric end of the stomach, when a partial gastrectomy was done."

To sum up, this man had a pylorectomy at 33 for cancer, and died a little more than seventeen years later, well beyond the five year limit of recurrence.[1] Only during the last year of his life did he have severe symptoms. An operation resulting in artificial feedings might have prolonged his life. This he refused.

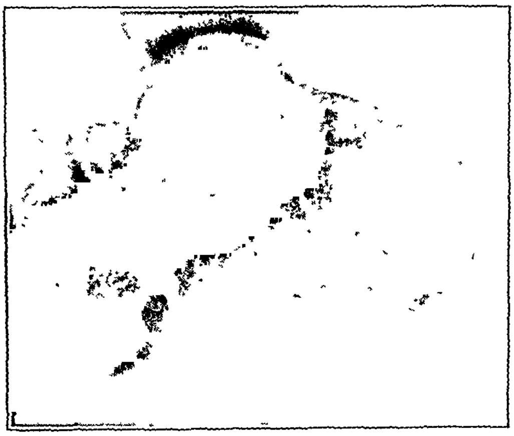
2007 Wilshire Boulevard.

UNUSUAL ARTICULATION OF THE ASTRAGALUS AND THE OS CALCIS

Charles E Farr, M D., New York

Many cases of lipping of the posterior edge of the astragalus are seen, and a few cases of an extratarsal bone are observed; but these are rare. The case here reported is unique in that it shows an extreme projection from the posterior surface of the astragalus, with a separate joint for this projection on a corresponding projection of the os calcis. Consultation with the anatomic department at Cornell University revealed no similar finding in their records.

The surgical significance of this unusual finding is obvious in that a slight trauma might easily fracture this projection and cause considerable temporary disability. I saw one such case in consultation, but the extra articulation was not present. The posterior projection of the astragalus was almost as marked as in the case presented.



Projection from posterior surface of astragalus, with separate joint for this projection on a corresponding projection of the os calcis.

This patient was a laboring man who had received a fairly severe contusion of the foot, and the roentgenogram was taken to exclude a fracture. No fracture was found, and the case is presented for its rarity and its possible complications.

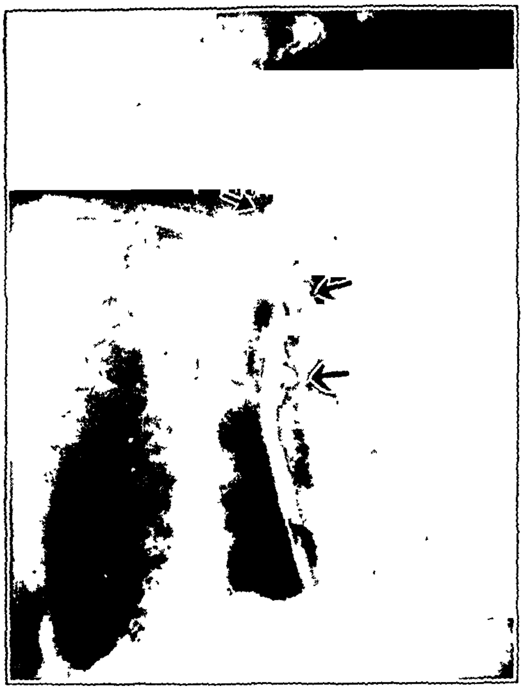
MULTIPLE SACCULATIONS OF THE ESOPHAGUS*

Jacob Buckstein, M.D., New York
Consultant in Gastro-Enterology, U. S. Veterans' Bureau; Associate Roentgenologist, Bellevue Hospital; Lecturer in Gastro-Enterology, New York Polyclinic Medical School and Hospital

The case described is reported because it is the first of its kind that I have seen in the course of more than 10,000 examinations of the gastro-intestinal tract.



Multiple sacculations of the esophagus, indicated by arrows.

T O., aged 44, complained of knifelike pain in the left upper quadrant, which occurred an hour or two after meals. The condition had lasted four months. There was no radiation, vomiting or food relief. He had lost 20 pounds (9 Kg.). Physical examination, except for tenderness in the left upper quadrant, was negative Nothing in the clinical examination suggested an esophageal disorder.

The sacculations of the esophagus in the accompanying illustration were noted in the course of a routine roentgenographic examination of the gastro-intestinal tract. The remainder of the alimentary canal was normal.

For a number of weeks since the examination, the patient has been entirely symptom free.

The esophageal condition does not appear to have any relation to his symptoms, and may be congenital.

1 West Eighty-Fifth Street.

Need of Periodic Health Examinations.—Individuals who need a periodic health examination at regular intervals are: 1. Healthy individuals who want to keep their health. 2. Near well individuals who think they are healthy but who are uncomfortable, dissatisfied, and who sometimes suffer pain. They have bad health habits, defects or impairments which, corrected, would place them in the healthy group. 3. Individuals who think they are ill, but who are merely the victims of bad physical and mental habits. 4. Unhealthy individuals who constantly have colds, boils or abscesses. They have defects, impairments and habits which need the attention of a competent physician. 5. Ill individuals with chronic disease or impairment which, treated properly, would prolong life and usefulness for many years.—Wood, T. D., and Dansdill, T.: By-Ways to Health, 1925, p. 7.

Special Article

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1008)

Essential Composition of Pills.—A pill mass consists of at least two parts: active ingredient and excipient. The active ingredient suitable for pill form is almost any solid medicine that is not deliquescent and the dose of which is small (not exceeding 1 Gm.). If the dose is higher than 0.5 Gm., two pills should be made of it. Even deliquescent substances may be prescribed if their dose is very small. Liquids can be prescribed in pill form, if the dose of the liquid does not exceed a drop.

A diluent is necessary when the dose of the active ingredient is very small, as 1 mg. of strychnine sulphate. Here the diluent (starch) is required to form pills of the proper size. Very irritant or caustic substances require a diluent in order to avoid excessive action on the stomach. Liquids and deliquescent bodies need an absorbent powder, such as kaolin. Also, a diluent is necessary if the substance is very soluble, as such pills are apt to flatten. Here, the addition of an insoluble vegetable powder to afford by its fibers and cell walls the mechanical support necessary to maintain the globular shape is advisable. One of the best diluents for this purpose is powdered glycyrrhiza. Powdered althea may be preferred, if white pills are wanted.

The excipient, or cohesive, varies with the nature of the basic ingredients. On the proper choice of the excipient depend the keeping qualities of the pills, which should be such that the pills will retain their shape, and that they neither harden nor soften, nor crumble with age. Sometimes the ingredients are rendered sufficiently adhesive by the addition of a few drops of water or of alcohol. Usually an adhesive must be used, among which glucose, extract of gentian, and glycerite of starch may be mentioned as probably the most generally useful. The physician should prescribe the excipient only when a special or unusual one is needed. Commonly, its choice may be safely left to the pharmacist. The determination of the quantity of excipient is always left to the compounder.

An instance when a special excipient is required is in case of those chemicals that are destroyed by organic substances, such as silver nitrate or potassium permanganate. For these, the usual diluent is kaolin, with petrolatum as the excipient; but these pills do not disintegrate readily. Marshall[38] proposes pills made with kaolin, 2 parts, and anhydrous sodium sulphate, 1 part, which, although very hard, disintegrate rapidly. As this method is not sufficiently well known, a brief description of it may be given here.

The powdered drug is mixed with the requisite amount of kaolin; half as much anhydrous sodium sulphate as kaolin is added and, after mixing, the whole is massed with about the same weight of water as of sodium sulphate. The mass must be kept above 33 C. until the pills are finished. When the temperature of the pills falls to that of the room, they become of stony hardness. The method depends on the fact that 33 C. is a critical temperature for sodium sulphate. Above that temperature the sodium sulphate exists in the anhydrous form; hence the water is free, and the mixture is a plastic mass. Below 33 C. the sodium sulphate exists as $Na_2SO_4 . 7 H_2O$. Hence, when the temperature falls, this hydrated salt crystallizes out and the pills rapidly become hard. The pills disintegrate quickly, owing to the ready solubility of this salt in water.

The simplest subscription being best, provided it is explicit enough, the formula "Mix and divide into pills" suffices. The word mix implies the making of a mass; otherwise it could not be divided into pills. When, however, a pill mass is to be encapsulated, "Mix, make a mass, and divide into capsules" should be the subscription. Otherwise the druggist might pack the powder into the capsule, with a resulting different timing and extent of action.

The pill mass, essentially a dough, is first rolled into a ball and then into a cylinder of the proper length to yield the desired number of pills when rolled under and cut by the opposing sharp ridges of the pill machine. They are finally made into perfect little balls by being rolled in a sort of wooden cover. A dusting powder (conspergative) of lycopodium—or starch, if the pills are white—is employed to keep the pills from sticking together.

Pill Coating.—Pill coating aims to disguise the taste and improve the keeping qualities of pills. The following coatings may be used:

(*a*) Gelatin coating is the most popular and probably the best, because the most easily soluble, coating for the great majority of pills. It is obtained by dipping pills in a strong warm solution of gelatin, which is then allowed to harden in the air. This process can be well carried out only on a large scale. It is generally not necessary to specify the kind of coating, as it really makes little difference in the action and may embarrass the pharmacist, who may have the identical pill on hand with a different coating. Should, however, gelatin coating be especially desired, it is specified by writing after the name of the pills, and enclosed in parenthesis, the initials for gelatin-coated, thus: (g. c.). A prescription for gelatin-coated vegetable cathartic pills would, for instance, be written:

℞ 12 vegetable cathartic pills, N. F. (g. c.)
Label: One or two at bedtime.

A gelatin coating quite as serviceable, if not as elegant, can be given pills by any pharmacist by the use of gelatin capsules, as previously noted.

(*b*) Sugar coating is produced by moistening the pill with mucilage of acacia; then quickly transferring to a porcelain capsule containing a mixture of powdered sucrose or lactose, 8 parts, and powdered acacia, 2 parts; and rapidly rotating until they are covered with a firm, white covering. Sugar coating can be satisfactorily carried out only by the manufacturer. Sugar coating is specified by writing (s. c.) after the number of pills ordered. If the porcelain capsule in which the pills are shaken contains cacao powder instead of the sugar mixture, cacao coating is obtained.

(*c*) Tolu coating is used by the Pharmacopeia and the National Formulary to protect delicate chemicals, such as ferrous iodide of phosphorus, against change on exposure to air. Such coating is obtained by rapidly rotating the pills in a porcelain capsule containing a little of a mixture of equal volumes of tincture of tolu and ether.

---

* This is the fifteenth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

[38] Marshall, C. R.: Manual of Prescribing, London, J. and A. Churchill, 1908, p. 187.

(*d*) Gold or silver coating, though much less frequently employed now than formerly, before gelatin or sugar coated pills were in use, may have a field of usefulness for its psychic quality, as well as because gold or silver can be easily applied by the retail pharmacist to insure tastelessness of extemporaneously prepared pills. Detailed directions for obtaining this coating are given in the National Formulary. By this means the pills become loosely coated with bits of broken foil, which effectively conceal the taste and yet give no obstacle to the penetration of solvents.

(*e*) Enteric pills are coated with a material that is insoluble in the stomach, but soluble in the intestine. Such coatings are: (1) keratin, made from goosequill; (2) phenyl salicylate; (3) "glutoid," gelatin hardened in formaldehyde, and (4) stearic acid coating. These coatings may be used when we desire action on the intestine alone, when the substance acts unfavorably on the stomach, or when the medicament is impaired in its action by the gastric secretion. Pills thus coated have, however, the disadvantage that it is impossible to regulate reliably the thickness of the coating and the rate of its disintegration. Hence they may not be dissolved in the intestine, and escape the body in the stools without having exerted the action expected of them. Enteric encapsulation seems preferable.

Administration of Pills.—Pills are swallowed as a whole, generally with the aid of a small quantity of fluid. Adults who think they cannot swallow pills are generally those who make the mistake of looking up while attempting to swallow. In this position, the swallowing of a bolus of food would be as difficult, if not impossible. The remedy lies in putting the pill far back on the tongue, taking a mouthful of water, and looking down while swallowing. Sometimes having the pill mixed with a little gruel seems to help in deglutition. A method that is said to succeed when others fail is to replace the seeds of a dark skinned grape with the pill, and then pop the pulp into the mouth and swallow it without chewing. All of which goes to show that it is not the size of the mass but the mental attitude toward it that is responsible for difficulty in swallowing pills or capsules.

POWDERS

Powders are finely subdivided solids or mixtures of solids. Their prescribing should be restricted to (*a*) comparatively insoluble, nondeliquescent drugs of inoffensive taste, such as bismuth subnitrate, magnesium oxide, calcium carbonate and sodium bicarbonate, and to (*b*) drugs, even though soluble, whose dosage is too bulky to be prescribed in capsules, chachets or solution, as the saline cathartics. Even soft or liquid substances may be prescribed in powder form, provided their dose is so small that it can be incorporated in a reasonable quantity of absorbing powder. Caustic or very irritant substances should not be given in this form, unless largely diluted with some inert powder, or unless the powder is dissolved in a liberal quantity of water before taking. A diluent is also necessary when the dose of the medicament is very small, as in the case of mild mercurous chloride, for otherwise the patient might not be able to find the dose. Enough diluent is added to make each powder weigh 0.3 Gm. Diluents available for these purposes are sugar of milk, cane sugar, oil sugars, powdered starch (which permits incorporation of at least 10 per cent of its weight of liquid) and powdered glycyrrhiza.

Unsuitable for administration in powder form are drugs and drug mixtures unstable in the air, such as:

(*a*) Deliquescent or hygroscopic bodies. Deliquescent are potassium acetate and carbonate; sodium iodide and nitrite; the halogen salts (chloride, bromide, iodide) of the alkaline earth metals (calcium, strontium, magnesium, lithium), of iron, zinc, manganese and gold; phenol, chromium trioxide, pilocarpine hydrochloride, and hyoscyamine hydrobromide. Hygroscopic are chlorinated lime, and scale preparations of iron and of pepsin.

(*b*) Liquefying mixtures: the phenols (phenol, thymol, resorcinol, camphor, menthol, phenyl salicylate). Acetanilid, acetphenetidin and antipyrine also liquefy with some of these; so do lead acetate and sodium phosphate.

(*c*) Volatile bodies and those compounds that are liable to decompose on exposure to air, as lead acetate and morphine acetate, which gradually lose acetic acid.

(d) Explosive mixtures; combinations of oxidizing and reducing agents, as potassium chlorate and sulphur.

The Pharmacopeia recognizes the following cathartic powder mixtures, mentioned in approximately descending order of practical importance:

1. Compound effervescing powder (seidlitz powder), containing sodium bicarbonate, 2.5 Gm.; sodium and potassium tartrate, 7.5 Gm., in blue powder paper; tartaric acid, 2.15 Gm., in white powder paper. The two powders are mixed with a half tumblerful of water before taking.
2. Compound powder of glycyrrhiza (compound licorice powder), containing: senna, 18 Gm.; glycyrrhiza, 24 Gm.; washed sulphur, 8 Gm.; *oil of* fennel, 0.4 Gm.; sucrose, 50 Gm. Average dose, 4 Gm.
3. Compound powder of jalap, containing: jalap, 35 Gm.; potassium bitartrate, 65 Gm. Average dose, 2 Gm.
4. Compound powder of rhubarb, containing: rhubarb, 25 Gm.; magnesium oxide, 65 Gm.; ginger, 10 Gm. Average dose, 2 Gm.

There is also in the Pharmacopeia the following formula for an analgesic diaphoretic which was popular before the days of the coal tar analgesics for the relief of the aches and pains of fever patients:

Powder of ipecac and opium (Dover's powder), containing: ipecac, 10 Gm.; opium, 10 Gm.; lactose, 80 Gm. Average dose, 0.3 Gm.

Dispensing of Powders.—Powders may be dispensed in bulk, or in divided doses.

When the dose of a powder exceeds 1 or 2 Gm., especially if its weight need not be very exact, it is best prescribed in bulk, the dose being measured, when wanted, with a teaspoon or in any other appropriate way. For the purpose of approximating dosage, it may be assumed that a heaped teaspoonful contains from 1 to 2 Gm. of a light powder; 2 to 4 Gm. of a moderately heavy, and 4 to 8 Gm. of a heavy powder. If level full, it contains only about half as much. Powders in bulk may be sent to the patient in a paper box or in a wide-mouthed bottle; the latter should always be selected, if the powder is liable to be altered by free access of air. The subscription would therefore either be "Dispense in a box," or "Dispense in a bottle," according to the permanence of the powder. Compound powder of glycyrrhiza is generally dispensed in a box. The effervescing salts should always be dispensed in a bottle.

Powders must be dispensed in divided doses whenever accuracy in dosing is necessary. This is the case with compound jalap powder and Dover's powder.

Each dose is then folded by the pharmacist in a powder paper. The dose accommodated by these may be quite large.

If the powders contain a volatile or a deliquescent substance, they must be wrapped in waxed paper, which may be specified in the subscription "Dispense in waxed papers." It is better, however, to avoid if possible prescribing such substances in powder form.

The patient may be directed to take the powder in water, milk or syrup, or he may place the dry powder on the tongue and swallow it with a mouthful of water. Insoluble bodies like bismuth subnitrate or chalk should always be stirred with water until all lumps have disappeared, as otherwise the formation of enteroliths is believed to be more likely. Powders are most conveniently administered to infants by dipping the moistened clean finger into the powder and spreading it over the infant's tongue.

The following special varieties of powders might be worthy of note:

Triturations (triturates): These are powders obtained by rubbing the active substance with some inert material, such as sugar of milk. Their advantage lies in the greater convenience of weighing a comparatively large amount of substance. Furthermore, the rubbing to a very fine powder increases somewhat the activity of sparingly soluble substances by exposing a greater surface to the solvent. Sparingly soluble, potent drugs are often best dispensed in this form. The Pharmacopeia contains a general formula for triturations, which is to be used by the pharmacist, unless he is otherwise directed:

The substance	10 Gm.
Lactose, in moderately fine powder	*90 Gm.*
To make	*100 Gm.*

The substance and the sugar of milk are weighed separately; then the substance, previously reduced, if necessary, to a moderately fine powder, is placed in a mortar, about an equal measure of lactose is added, well mixed by means of a spatula, and triturated thoroughly together. Then fresh portions of the lactose are added, from time to time until the whole has been incorporated, and trituration is continued until the substance is intimately mixed with the lactose and reduced to a fine powder.

Perhaps the best example of the use of a trituration is in the prescribing of elaterin, the dose of which is so small (0.003 Gm.) that the addition of lactose is required to divide the substance into powders of suitable size. In prescribing a hydragogue cathartic for dropsy, we might add to the trituration of elaterin 0.02 Gm. of extract of hyoscyamus per dose to antagonize griping. One powder might be taken on alternate mornings.

Mild mercurous chloride is likewise often prescribed as a triturate, for calomel is so heavy and the quantity usually employed so small that, without the addition of lactose, the patient might not be able to find his dose.

Oil Sugars: Oil sugars are mixtures of volatile oils with powdered sucrose. The National Formulary contains a general formula for these: any volatile oil 1 drop; sucrose, 2 Gm. The sugar is triturated with the volatile oil until they are intimately mixed. Thus oil sugar of anise or of peppermint is prepared from the corresponding volatile oil, according to this formula. They should be freshly made, when wanted. They are used mainly as pleasant diluents for powders.

(To be continued)

New and Nonofficial Remedies

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application. W. A. Puckner, Secretary.

MEAD'S POWDERED LACTIC ACID MILK (CULTURED).—A modified milk product prepared by fermenting whole milk with *B. acidi-lactici*, drying, and powdering. Each 100 Gm. contains approximately protein 29 Gm.; carbohydrates, 26.4 Gm.; fat, 28.8 Gm.; free lactic acid, 3 Gm., and ash, 6 Gm.

Actions and Uses.—Mead's powdered lactic acid milk (cultured) is proposed for overcoming the so-called buffer action of cow's milk in the infant's stomach. The nutritive value of 500 Gm. corresponds approximately to 2,450 calories.

Dosage.—For use, Mead's powdered lactic acid milk (cultured) is mixed with warm water in quantities as prescribed by the physician. A smooth thin paste is made by adding a small amount of water to the dry powder; then the remainder of the water is added, and the resulting product bottled and kept on ice.

When prepared for use in proportion of one part solids to seven parts water, Mead's powdered lactic acid milk (cultured) contains approximately fat, 3.6 per cent; carbohydrates, 3.3 per cent.; protein, 3.6 per cent, and ash, 0.75 per cent. The nutritive value of 500 Gm. is approximately 319.2 calories.

Manufactured by Mead Johnson & Co., Evansville, Ind. No U. S. patent or trademark.

MEAD'S POWDERED LACTIC ACID MILK (ACIDIFIED WITH LACTIC ACID U. S. P.).—A modified milk product prepared by adding lactic acid U. S. P. to whole milk, drying and powdering. Each 100 Gm. contains approximately protein, 26.4 Gm.; carbohydrates, 34 Gm.; free lactic acid, 3 Gm.; fat, 24 Gm., and ash, 6 Gm.

Actions and Uses.—Mead's powdered lactic acid milk (acidified with lactic acid U. S. P.) is proposed for overcoming the so-called buffer action of cow's milk in the infant's stomach. The nutritive value of 500 Gm. of the dry powder corresponds approximately to 2,345 calories.

Dosage.—For use, Mead's powdered lactic acid milk (acidified with lactic acid U. S. P.) is mixed with warm water in quantities as prescribed by the physician. A smooth thin paste is made by adding a small amount of water to the dry powder, then the remainder of the water is added and the resulting product bottled and kept on ice.

When prepared for use in proportion of one part solids to seven parts water, Mead's powdered lactic acid milk (acidified with lactic acid U. S. P.) contains approximately fat, 3 per cent; carbohydrates, 4.2 per cent; protein, 3.3 per cent, and ash, 0.75 per cent. The nutritive value of 500 Gm. corresponds approximately to 335 calories.

Manufactured by Mead Johnson & Co., Evansville, Ind. No U. S. patent or trademark.

POLLEN EXTRACTS-MULFORD (See New and Nonofficial Remedies, 1925, p. 285; The Journal, June 6, 1925, p. 1734).

Lamb's Quarters Pollen Extract-Mulford; Ragweed Pollen Extract (Fall)-Mulford; Timothy Pollen Extract (Spring)-Mulford; Wormwood Pollen Extract Mulford. Also marketed as:

Fourth Series: Five glass syringes (doses 16 to 20, inclusive), each containing 1,000 protein units.

CONCENTRATED POLLEN EXTRACTS-SWAN-MYERS (See The Journal, May 30, 1925, p. 1634; Jan. 23, 1926, p. 277; Feb. 27, 1926, p. 625).

These products are also marketed in 2 cc. vials and in sets of five capillary tubes for diagnostic tests, each tube containing sufficient extract for one test.

SCARLET FEVER STREPTOCOCCUS ANTITOXIN (See The Journal, May 2, 1925, p. 1338).

E. R. Squibb & Sons, New York.

Scarlet Fever Streptococcus Antitoxin Concentrated (See The Journal, Jan. 16, 1926, p. 199).—Also marketed in packages of 1 cc. vials (for the diagnostic blanching test) containing sufficient scarlet fever antitoxin for ten blanching tests.

A CRITICISM OF MODERN MEDICINE

A conscientious reviewer of the history of medicine would probably admit that within the last century, and largely within half that period, medical science and art have advanced with a speed incomparably greater than at any previous time. Philosophical speculation has given way to experimentation as medicine has kept pace with the advancement of science in general. It would be as ungracious as it is unjust to deny the great advance of medical knowledge along with the evolution of culture; and medicine can proudly boast of many conquests that deserve to be called marvelous.

Synge[1] has urged that it is often more useful to criticize than to applaud, because without dissatisfaction, without criticism, progress is impossible. To be content is to cease to advance. Synge has therefore frankly presented a series of cogent criticisms and comments, some of which seem worth repeating at a time when the needs, the shortcomings, the failures and the misdirections of medical training are being investigated vigorously in several quarters. There can be no offense in any effort to promote an advance, particularly since, despite medical progress, the incidence of all diseases is not decreasing; in fact, the incidence of some diseases is markedly increasing. Like many writers in this country, Synge stresses the belief that the tendency of modern diagnosis is to neglect the evidence furnished by signs and symptoms, and to place undue reliance on special tests. Thus, we are told bluntly that the roentgen ray, by simplifying diagnosis, has made clinicians lazy. "The science of errors is, unfortunately, a neglected branch of study." This statement embodies an appreciation of the readiness of present-day student and practitioner alike to accept so-called evidence at face value and without adequate discussion. Thus, some serologic reactions are frankly misleading. We are, in Synge's judgment, too ready to apply unfinished biochemical researches to clinical purposes. A discovery is heralded, and straightway it is applied to purposes of diagnosis or treatment regardless of possible limitations or fallacies. "The methods fail; the biochemist gets the abuse." Biochemists and clinicians do not collaborate sufficiently.

It sounds like a platitude, yet one welcomed by the "practical doctor," to hear that observation, experience and sound judgment are more important in clinical medicine than are measurements with delicate instruments. We have often maintained that the use of helpful material devices is not incompatible with the exercise of sane judgment. Even the most "hard headed" physician usually finds a watch helpful in estimating the behavior of the heart. We find somewhat greater sympathy with Synge's animadversions at the spread of certain fashions and foibles. Vaccines become a panacea, and every conceivable disease is treated with them. Drugs must now be given hypodermically or intravenously instead of by mouth, because a few drugs have been found to be more efficacious when so given. And, with the age of endocrinology, prosperity has come to new forms of pseudoscience.

Synge alleges, with much justification, that the belief in the magical and the irrational has increased because the critical faculty has been dulled by so many new wonders. The pessimist will be inspired by the assertion that belief in everything is followed by belief in nothing; credulity is succeeded by skepticism; skepticism by cynicism; cynicism makes no effort, knowledge declines. Is it not better to share the more optimistic outlook of Synge in this admonition:

> Hard and conscientious work, accurate observation, sound reasoning, a mind free from obsessions and superstitions, a firm belief in the possibilities of medicine as an art and as a science; these are the things which have raised medicine to its present greatness; these are the things which will carry it onward, always.

ACRODYNIA, ERYTHREDEMA OR SWIFT'S DISEASE?

It was once an almost universal custom to associate a newly recognized disease entity with the name of the investigator, usually a clinician, who first published an accurate description of it. Thus, to give only a few conspicuous illustrations, physicians still speak of Bright's disease, Pott's disease, Basedow's disease, Barlow's disease and Paget's disease. Obviously, a step in advance occurs when any malady can be more accurately designated as a demonstrable lesion of some organ, a definite perversion of some function, or a bacterial invasion of certain tissues. Interstitial nephritis, hyperthyroidism, and tuberculosis of the spine have direct implications of a more scientific character. So long as a disease designation can be based on a definite, clear cut, pathogenic feature, the corresponding name is likely to represent a distinct advantage. Often the nomenclature refers merely to a conspicuous symptom. Eczema and "pink disease" represent instances of the undesirability of the designations. Symptoms are all too often common to more than one systemic disorder and consequently do not have a uniform ultimate cause.

---

[1] Synge, V. M.: A Criticism of Modern Medicine, Irish J. M. Sc. 6:20 (Jan.) 1926.

The history of the confusion and actual harm arising from this more modern practice of employing supposedly "scientific" technical language has been exemplified in the discussions of a recently well recognized pathologic entity of infancy and early childhood. The clinical syndrome consists of three groups of symptoms, nutritional, nervous and cutaneous, occurring in infancy and early childhood, such as loss of weight and appetite, weakness, extreme irritability, sleeplessness, paresthesias, loss of reflexes, photophobia, paresis, erythema, swelling, cyanosis, coldness of hands and feet, high blood pressure, excessive perspiration, miliaria, desquamation, loss of hair and loss of teeth. Recently it has been designated occasionally under the name acrodynia, a term referring to the painful extremities. This obviously describes one of the most typical symptoms of the complex, although it gives no indications of the nutritional or neurologic involvements in the causation. Another recent designation is erythredema, a term likewise applying to a prominent clinical feature seen in the pink hands and feet.

Recently it was pointed out[1] that the disease here referred to is by no means uncommon. Australia, England, Netherlands, Scotland, New Zealand, Sweden and Switzerland have furnished patients in addition to those of American pediatricians. At least 230 cases are thus recorded for consideration. Warthin[2] has referred to all the current designations as unfortunate and misleading. His own necropsy studies indicate, for example, that the expression erythredema is not universally justifiable in this connection, for his histologic observations at the University of Michigan failed to disclose any edema of the corium. They do not present any evidence as to a specific infectious etiology; they likewise show no relationship between tonsillar disease and the syndrome, in contrast with Rodda's[3] indications. Two cases, representing Warthin's important contribution, are too few to permit broad generalization. The changes in the skin and central nervous system suggested to him at once the pathology of the early erythema stage of pellagra. The changes in the skin are also identical with those seen in certain forms of light sensitization, xeroderma and fagopyrism, as well as with certain stages of roentgen-ray and ultraviolet ray erythemas. The entire anatomic picture in the two cases suggests either a food deficiency or a toxic state acting on persons of the hypoplastic constitution, affecting the reticulo-endothelial system of meninges and skin, also the vegetative nervous system, and possibly leading to a light sensitization. With an important subject thus clearly remaining *sub judice,* Warthin proposes that, pending more adequate investigation and conclusive evidence of etiology, it would be better to call the condition Swift's disease than to designate it by terms that apply so little to it as do "acrodynia" or "erythredema." This reference is in deference to the circumstance that Swift, in 1914, under the clinical designation of erythredema, reported at the Australian Medical Congress fourteen cases presenting the now familiar clinical picture of red hands and feet occurring in infants and young children.

INVESTIGATION ON STREAM POLLUTION

Increasing density of population brings with it one penalty that cannot be escaped, an increase in the amount of waste from human bodies which must somehow be permanently removed. One of the simplest methods of sewage disposal is to turn the sewage into some body of water so large that oxidation processes may go on and a nuisance be avoided. This practice was long fraught with disastrous consequences to drinking water supplies, and in the generation before methods of water filtration and chlorination were worked out and applied, typhoid and kindred diseases ran riot. Although water-borne typhoid in this country is now largely a thing of the past, there are signs that the pollution of many streams is again approaching a danger point.

When the pollution of streams reaches a certain stage, it becomes more difficult and in some cases impossible to utilize the water for domestic use. There is no need to set up an impracticable ideal. The fact that nearly every body of surface water large enough to serve as a source of water supply is more or less contaminated must be faced. If the water does not receive city sewage, it is well-nigh certain to receive the drainage from small towns and villages or from isolated farmhouses. Even in remote districts, as experience has shown, the streams are exposed to occasional contamination by camping parties or chance wayfarers. The running streams of this country are not now in a safe condition to use as sources of water supply without some sort of purifying treatment. The same is true in greater or less degree of most ponds and lakes.

While our present methods of water purification are in most instances quite adequate, they should not be expected to effect the impossible. Sooner or later the increase of pollution may place a burden on the purification process that cannot be successfully met. When that time comes, "accidents" to the water supplies will become increasingly frequent and the menace of water-borne diseases will again hang over us. There are signs that in some localities this period may not be remote.

This reference is in deference to the circumstance that Swift, in 1914, under the clinical designation of erythredema, reported at the Australian Medical Congress fourteen cases presenting the now familiar clinical picture of red hands and feet occurring in infants and young children.

INVESTIGATION ON STREAM POLLUTION

Increasing density of population brings with it one penalty that cannot be escaped, an increase in the amount of waste from human bodies which must somehow be permanently removed. One of the simplest methods of sewage disposal is to turn the sewage into some body of water so large that oxidation processes may go on and a nuisance be avoided. This practice was long fraught with disastrous consequences to drinking water supplies, and in the generation before methods of water filtration and chlorination were worked out and applied, typhoid and kindred diseases ran riot. Although water-borne typhoid in this country is now largely a thing of the past, there are signs that the pollution of many streams is again approaching a danger point.

When the pollution of streams reaches a certain stage, it becomes more difficult and in some cases impossible to utilize the water for domestic use. There is no need to set up an impracticable ideal. The fact that nearly every body of surface water large enough to serve as a source of water supply is more or less contaminated must be faced. If the water does not receive city sewage, it is well-nigh certain to receive the drainage from small towns and villages or from isolated farmhouses. Even in remote districts, as experience has shown, the streams are exposed to occasional contamination by camping parties or chance wayfarers. The running streams of this country are not now in a safe condition to use as sources of water supply without some sort of purifying treatment. The same is true in greater or less degree of most ponds and lakes.

While our present methods of water purification are in most instances quite adequate, they should not be expected to effect the impossible. Sooner or later the increase of pollution may place a burden on the purification process that cannot be successfully met. When that time comes, "accidents" to the water supplies will become increasingly frequent and the menace of water-borne diseases will again hang over us. There are signs that in some localities this period may not be remote.

With this situation in mind, the U. S. Public Health Service about twelve years ago inaugurated a study of stream pollution. Under wise guidance the investigations have included not only the nature and degree of the pollution, but the proper criteria of water purity and water purification, the complex and highly important phenomena of natural purification, and the efficiency of filter plants in dealing with water overloaded with sewage. Many technical papers dealing with various phases of the work have been published, and a general review has recently appeared.[1] The comprehensive studies on the Ohio River especially have demonstrated in a convincing way the great extent to which we must depend on processes of natural purification for safeguarding our water supplies. It was shown twenty-five years ago, during studies on the Chicago Drainage Canal, that the sewage bacteria decreased at orderly rates as the time from the point of initial contamination increased, and that these rates were affected by seasonal influences. These results have been amply confirmed by the recent work of the Public Health Service on the Ohio and Illinois Rivers. The factors that cause this reduction, however, are still not clearly understood. Among the interesting suggestions made is that one, if not the most significant, agency is the activity of the plankton animals in destroying bacteria.[2] It is evident that an important task before workers in this field is the determination of the factors governing natural purification in order that this process may be taken advantage of to the fullest extent.

Water filters and other devices for large-scale purification cannot be relied on to convert highly polluted streams into good drinking water. Apart from esthetic considerations, there is a limit to what can reasonably be demanded from any filter plant or chlorination apparatus. Since in spite of these limitations stream pollution tends to increase with increasing urban growth, there are two main possibilities: either artificial sewage treatment must be practiced on a larger and more expensive scale, or the processes of natural purification, as exemplified in storage, must be utilized in increasing degree. Something can probably be done to enhance the effectiveness of artificial methods of water purification, but the sudden and extreme variations that occur in the "load" when pollution is extreme constitute a serious difficulty. All in all, the questions of water standards, of the reliability, adaptability and limitations of purification processes set to deal with varying loads, and of the laws of the self-purification of polluted streams form a group of problems the importance of which to sanitary science can hardly be overestimated. It is to be hoped that the series of studies conducted with such signal success by the representatives of the Public Health Service will be continued and, where desirable, extended.

RENAL VASOCONSTRICTION AND ALBUMINURIA

Complete interruption of the arterial flow in the kidney for a short time is followed by albuminuria. The glomerulus of the kidney has been demonstrated to be one, at least, of the structures through which escape of protein into the urine may take place when the renal circulation is interfered with. Recent studies, notably those of Richards of Philadelphia and his co-workers, have demonstrated an unsuspected intermittence of blood flow in some of the glomeruli, so that the circulatory activity of one is independent of others. This is analogous to what Krogh of Copenhagen described with respect to the behavior of capillaries in muscle tissue. Like the latter, apparently the glomeruli do not all ordinarily receive blood simultaneously. In his Harvey Society Lecture of 1921 on kidney function, Richards[1] remarked that if intermittence of glomerular flow is a normal phenomenon, it would appear that albuminuria might occur if, for any reason, the duration of the normal intermittent cessation of flow increased. How well this conjecture was warranted is indicated by Starr's[2] observations at the University of Pennsylvania. In animals, agents causing renal vasoconstriction were found to cause a transient albuminuria. In man, the same manifestation followed the use of the drug ephedrine, which is not intrinsically injurious to the kidney and which has been demonstrated to produce renal vasoconstriction. Albuminuria failed to appear in those cases in which signs of circulatory change were lacking. According to Starr, the observed facts may be explained by the conception that renal vasoconstriction causes increase in the duration and extent of the normal intermittent interruptions in the glomerular circulation. Permeability of the glomerular membranes is so increased by these interruptions that, when blood flow is reestablished, albumin escapes. Such an interpretation of what has been termed non-nephritic albuminurias may be applicable to a variety of conditions seen in man. The fundamental feature is not the mere diminution in the rate of blood flow that was once held responsible for the phenomena, but rather the intermittent interruptions in blood flow through the glomeruli, the duration of which is greater than can be borne by the glomerular membranes without asphyxial alteration in their permeability. As Starr has pointed out, this may apply to the albuminurias that result from excessive muscular exercise or emotion or that are produced reflexly. It may play a part in the explanation of the albuminuria that occurs after anesthesia or in cardiac decompensation; and it may represent a reason for the occasional occurrence of protein in the urine of the healthy. There are many ways in which the sequence of renal vasoconstriction, anemia, localized tissue asphyxia, and escape of albumin may be conceived to arise independent of any frank disease of the kidney parenchyma. These experiments, as Starr points out, provide a reason for anticipating the appearance of protein in the urine whenever profuse urine secretion is reestablished after a period of relative or complete suppression as the result of constriction of vessels of the kidney.

CONVICTED DIRECTOR OF EDUCATION NOW SEEKS HIGHER OFFICE

Reports indicate that William H. H. Miller, who in 1921-1922 was director of registration and education of Illinois, is now aspiring for the office of congressman-at-large. In his former position he became involved in a scandal because of a traffic that was being carried on in state licenses for physicians and pharmacists,[1] and was indicted by a Cook County grand jury and thrown out of office.[2] The bill returned by the grand jury named not only William H. H. Miller but also K. A. Fries and Dr. N. Odeon Bourque. K. A. Fries, employed in the department, was said to be Miller's son-in-law. Dr. N. Odeon Bourque was then prominently connected with the Chicago Medical School, a class C institution, in Chicago, and was conducting a quiz class in which he openly guaranteed that questions presented to the class would include a high percentage of the questions actually asked by the state board—a claim supported by a comparison of the questions. In the trial, July 21, 1922, Miller was declared guilty of conspiracy and was fined $1,000, which was paid in open court two days later.[3] Miller now has the presumption to seek nomination as congressman-at-large from Illinois. The people of Illinois may judge whether his record warrants their support of his candidacy to represent them in Congress.

ARCHIVES OF DISEASE IN CHILDHOOD

When the Board of Trustees began the publication of the *Archives of Internal Medicine* in 1908, few physicians anticipated the progress that the American Medical Association would make in the publication of special periodicals. Today, special journals in internal medicine, diseases of children, diseases of the skin, neurology and psychiatry, surgery, otolaryngology and pathology testify to the worthiness of the work. Every physician practicing in these specialties is ready to admit that the publication of these periodicals has done as much perhaps as any other factor in advancing progress in the fields they cover. A new and significant recognition of the place made by these publications is the fact that the British Medical Association has just issued what will probably be the first of special journals which it proposes to publish. In an introductory statement, Sir Thomas Barlow indicates the value of such a periodical to the progress of science, pointing out many problems in the diseases of children which demand investigation, and the necessity for bringing together the conclusions obtained by various workers, giving them at the same time opportunity to present their work. The first number of the British periodical is excellently printed on coated paper, and the articles are handsomely illustrated, with some of the pictures in color. The contents are limited to original contributions in the field of pediatrics. The editors selected by the British Medical Association are Hugh Thursfield and Reginald Miller, and there is a consulting staff, including seven other leading specialists in the diseases of children, and the editor of the *British Medical Journal.* It is well that English periodical literature should have another distinguished representative of the type of the *Archives of Disease in Childhood.*

ANNUAL CONGRESS ON MEDICAL EDUCATION, MEDICAL LICENSURE AND HOSPITALS

Held in Chicago, Feb. 15, 16, 17 and 18, 1926

(Continued from page 1078)

FEBRUARY 17—AFTERNOON

Medical Legislation in Connecticut

DR. ROBERT LEE ROWLEY, Hartford, Conn.: The investigation started by the public press in the "home town" of one of the diploma mills, and how the emissary came and told our governor of some of the startling discoveries made, and the prompt action taken by the governor, are matters of recent history. In our state there had been indications—noted by some—that all was not well, and when this was brought to the attention of the state medical society four of its members were delegated to lay the situation as it then appeared before state authorities. That was done just about one year before any action or investigation on the part of the state was undertaken. To the Council on Medical Education and Hospitals is due the credit for having been apparently the first to recognize the fact that graduates of low grade medical schools were coming in increasing numbers to one of the examining boards in our state, where they seemed to experience little if any difficulty in meeting the requirements that enabled them to obtain licenses. The investigation in Connecticut resulted in the cancelation of about 168 licenses to practice. Nearly three fourths of the persons holding those licenses resided outside Connecticut. Appeals were made in about sixty cases against the decision for cancelation of licenses. These cases are still in the courts, and, pending final decision on the appeals, those persons may continue to practice, according to a ruling of the attorney general. At the session of the state legislature, a year ago, bills were introduced for the restoration of licenses in about fifty of the cases. All those bills were defeated.

The state chamber of commerce prepared a bill that became the ground work of the bill that was finally approved and presented to the legislature by the grand jury. Perhaps the most important feature of the so-called grand jury bill was the one that provided for one examining board with one standard for all applicants for licensure to practice in any branch of the healing art. The fairness of purpose of the sponsors of that bill is illustrated by the provision that the examination shall be so conducted as not to discriminate against the views of any bona fide organization, sect or school, as to remedies or treatment or any system of therapeutics. The grand jury bill was defeated; instead of the six examining boards being replaced by one board, we now have in Connecticut seven examining boards. This seems absurd, but, as a matter of fact, an important step in the right direction has been taken. The state board of healing arts came into being, July 1, 1925. Under the terms of this law the governor appoints the three members of the board, one of whom is to serve for two years, one for four years and one for six years. No one can be appointed to the board who has received a degree in any of the healing arts, or who is a trustee, director, officer or employee of any hospital. The new law provides that every person desiring "to take an examination" to be admitted to practice any branch of the healing art must show by written examination by this board that he has a comprehensive knowledge of anatomy, physiology, hygiene, pathology and diagnosis. To be admitted to the examinations, he must satisfy the board that he is a person of good moral character and that he was a graduate of a high school or possessed equivalent educational qualifications before he began the study of the healing art. The board conceives its function as a board of elimination, a coarse seive through which applicants for a license to practice the healing art must first pass, with consequent elimination of the obviously unfit. The new law provides that a certificate from the state board of healing arts is prerequisite to examination by the Connecticut medical examining board, the Connecticut homeopathic medical examining board, the Connecticut eclectic medical examining board, the state board of osteopathic registration and examination, the state board of chiropractic examiners, or the state board of naturopathic examiners. It is too early to say whether or not any significance attaches to the fact that thus far, with I believe one exception, all the applicants before the board of healing arts have been graduates of regular schools of medicine. One would have supposed that a number of graduates of other schools would have appeared for examination before this time. It may be that the high school education requirement is a little too much of a hurdle for some.

Fraudulent Medical Diplomas, and How Some Holders Secured Licenses

Frederick C. Waite, Ph.D., Cleveland: It is only the choice, the valuable, the desirable things that are counterfeited. With the great improvement in medical education in the twenty-five years just past, the genuine medical diploma has come to be in the public mind one of the most highly prized professional hall marks of our modern life. It is no wonder that a market for fraudulent medical diplomas has arisen and develops into a commercial enterprise. In one of the states in which were two of the principle foci of these activities, it has been my privilege to work with the public authorities in the study of the methods and results of the short cut into the medical profession through fraudulent diplomas. From such a consideration emerge certain principles which should be written into the creed of each licensing board. There is no justification in accepting a graduate of a deficient school. Every board should possess itself of frequently corrected knowledge of the educational efficiency of all those schools whose graduates commonly appear before it. In the case of the schools in its own state, that knowledge should be intimate. Graduates of little known schools or of schools of foreign countries should be denied admission to examination until authentic information is secured. Every board should have accessible data from which it can advise boards of other states as to intimate details of all schools within its own state, either now or previously existing. A postgraduate or ad eundem or duplicate degree should not be accepted as evidence of proficiency except after careful inquiry. No honorary degree should be accepted as giving evidence of proficiency. The recommendations as to personal worth and moral character should be investigated to ascertain just how much each sponsor knows about the candidate and also as to the professional standing of the sponsors themselves and the worth of their judgment. The authenticity of statements as to preliminary education should be directly investigated, and it should be insisted that this education shall have been completed before the professional course was begun. Preliminary education authenticated by examination to establish an equivalent should immediately create suspicion. Application blanks should be revised in various respects, especially to establish scholastic accomplishment instead of mere record of time service through attendance. Applications for license should be postponed or refused when presented too late to permit thorough investigation. No one expects that the end of fraudulent medical diplomas has arrived. The orgy of the last few years would have been improbable had the statutes of the various states been adequate; and, were the present statutes sufficient, each participant could be commensurately punished. Now, while the danger is in the public mind, is the proper time to prepare for the next crop of diploma mill products. It is the duty of each state board to cooperate in, and inaugurate, if necessary, the endeavor to secure in its own state legislation making it a felony to participate in the issuance, selling or receipt of an unearned diploma of medicine or of any other profession that relates to public health.

Revocation of License

Dr. K. P. B. Bonner, Morehead City, N. C.: The unworthy licentiate is a menace to the public, a discredit to the profession and a reflection on the licensing board. The agency vested with the power of licensing should have the power of unlicensing where necessary. Habitual imtemperance, convictions in court of crimes involving moral turpitude, criminal abortion, fraud and unprofessional conduct are generally accepted among the states as sufficient grounds on which a license may be withdrawn. These are named in the order of their popularity, and are specifically incorporated in the laws of thirty-eight, thirty-five, thirty and twenty-seven states, respectively. Demoralizing and deceptive advertising and gross immorality are less generally recognized as causes. Many states have set up in the statutes obviously just causes for revocation of license, but have made the enforcement of the law almost impossible by the insertion of a useless qualifying clause. It is surprising how limited are the causes for action in some states. Two states have no provisions of law permitting a license to be revoked. Direct correspondence with these boards reveals that licenses are revoked in each of these states. It would be interesting to know how the courts would view such procedure on appeal from the decisions of these boards. The section permitting withdrawal of license should be brief, but at the same time should cover every phase of misconduct. As far as possible, the board should have wide discretionary powers, and it should be made clear that such powers were vested in it. If too many qualifying clauses are inserted, it is possible that the primary object of the law will be defeated. The necessary machinery should be set up legally providing for the conduct of hearings, and investing the board with the power to issue summonses and to administer oaths. Above everything else, the power to revoke a license should be vested in the board. The law should provide, in cases of guilt, for degrees of punishment. With such discretionary powers, there is no necessity of making provision for future restoration of license.

Annual Registration of Physicians: Reregistration in Iowa

Dr. Don M. Griswold, Des Moines, Iowa: In 1906 there were about 5,000 persons practicing medicine in the state of Iowa, as nearly as can be estimated. Shortly after this date the work of the committee of medical education of the American Medical Association began to be felt. The supply of poorly trained physicians was being shut off at its source. It can be said with truth and justice and should be proclaimed from the housetops that the medical profession has "cleaned its own kitchen." As a result of the tireless and unceasing work of its board members, who were guided and directed by the Council on Medical Education of the American Medical Association, this important work has been done. The barriers at the front door of our profession are sufficiently high and sufficiently strong to withstand any assault. This state of affairs gives us time to look about for the other avenues of entrance than the "front door." Every fraudulently used license that is not meaningless or an outright forgery has been issued honestly to some one. These licenses that have no termination go on serving a purpose for some fraud, years after the man who earned it was sleeping in his grave. The license of a dead physician may be innocently sold as part of the assets of an estate. To frustrate this entrance from the "side door," several states, including Iowa, require an annual reregistration of the license to practice medicine. The holder of each license is addressed annually and asked whether he wishes to use his license during the coming year. If he does, he pins his check for one dollar to the enclosed card and returns it to the office of the board. If the licensee has died, retired, moved away or for any other reason does not receive the notice, the postmaster, family or friends notify the board and proper record is made of the fact.

DISCUSSION

DR. T. J. CROWE, Dallas, Texas: Men are going about the country, or were, using old diplomas and using old license certificates, simply taking out the name and inserting the name of another man, many of whom had been dead twenty years. Texas has tried to overcome that thing by issuing its license certificate on bank note paper, so that it cannot be changed or erased without detection. Dr. Waite's work, I think, was well done, but I think he made rather a doubtful use of it in publishing to the world that the state boards of this country are of doubtful caliber.

DR. JAMES STEWART, Jefferson City, Mo.: Dr. Waite's paper was one of the most interesting papers that I have heard. I have heard a lot about diploma mills. I want to add one more mill, and that is the state certificate mill. I want to ask you how can all of these men who have graduated from these inferior schools and from schools of no standing whatsoever, without any premedical education, come before state boards of health and get state certificates to practice medicine? There have been numbers of men in Missouri, and I guess elsewhere, who have paid all the way from $250 to $2,800 for state certificates to practice medicine.

DR. DAVID STRICKLER, Denver: I think it is very desirable that the annual registration should be carried out in Colorado. We have no data in our office to tell how many of these frauds are in the state at the present time. I should like to know whether in annual registration returns you simply give the name and address of the physician or whether you give any information as to the school he graduated from and when. The conditions on which he was licensed, it seems to me, would be good information.

DR. HENRY W. BRIGGS, Wilmington, Del.: The function of a state examining board is just as much to look after the men after they have been licensed as to license them, and, if necessary, to take their license away from them when they become unworthy. In the matter of interstate endorsement: If a man comes from a state the standard of which is equal to our own, and comes with proper training, premedical and medical; if he has had one year's internship in an accredited hospital, and has the recommendation of his own state board, signed by one of the officials, under seal, we will endorse the license without inquiry as to whether that particular state will take one of our men. In my state we have compulsory annual registration and it works very much to our advantage. Every physician in our state, in lieu of a state tax on any real estate which he might own, must pay to the state $10 for the privilege of practicing in that state that year. After the first day of June of each year, nobody is licensed in that state until he renews his license and registers with the clerk of the county in which he happens to live.

DR. H. M. PLATTER, Columbus, Ohio: Class C schools have not been on the accredited list of the Ohio state board. Two years ago we interrupted a diploma mill at Marietta. We have to be constantly on the alert to prevent the certificates of physicians who have died being sold, to a new physician who never saw a medical college. We have our troubles in examinations. Last year we threw two out for cheating. Not one of us is so smart that he cannot be imposed on.

DR. C. C. PIERCE, Chicago: There is not at the present time nor has there ever been a graduate of any other than a class A school in the commissioned corps of the Public Health Service. After the war, the Public Health Service was authorized to recruit a reserve corps. We took in about 1,500, practically all of them ex-service men. We enrolled these men without examination, on the strength of their army service and the credentials they presented. I know of one instance in which a graduate of the St. Louis College of Physicians and Surgeons was accepted to do laboratory work in a Veterans' Bureau hospital. That man, however, is no longer connected with the service.

DR. HAROLD L. RYPINS, Albany, N. Y.: In the first place, registration must be annual. In the second place, it must raise enough money so that the administrator will have funds to investigate illegal practitioners. In the third place, the statute must be worded so that a man not having a license and not on the annual printed list will be automatically proved an unlicensed practitioner. In the fourth place, there must be permanent, efficient machinery for carrying out attacks against those who do not appear on the annual registration list.

DR. I. D. METZGER, Pittsburgh: The state of Pennsylvania last year passed a reregistration act which made necessary the tabulation of all the persons in the state licensed for the practice of the healing art. That includes not only physicians but also osteopaths, druggists and therapeutists. It also includes chiropodists and physiotherapists. There are some 13,000 in the state of Pennsylvania. A fee of $1 in charged.

DR. AUGUSTUS DOWNING, Albany, N. Y.: The members of every profession in the state of New York, including architects and engineers, have to register annually. This annual registration acts as a drag-net, and sooner or later every illegal practitioner is caught.

DR. ROBERT L. ROWLEY, Hartford, Conn.: We do not have an eclectic examining board in Connecticut at this time, which is due not to the fact that the law has been changed but to the fact that the governor has been unable to find enough members in the eclectic medical society to fill the appointments on the board. I think our troubles are at an end for a time.

FREDERICK C. WAITE, PH.D., Cleveland: You would think I had disclosed something here. Anybody who has subscribed for THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and has bought the directory has all the figures I have given. I have simply compiled them.

DR. DON M. GRISWOLD, Des Moines, Iowa: We send to the county medical society only the names and addresses and ask for corrections on that list. As to the funds for financing this measure, the money collected should be kept in a separate fund for carrying out the purposes of the act that was effective in collecting it, or else it should be put back into the general funds of the state, with the hope that a comparable sum will be made available to the department for carrying out the purposes of the act. Our state is essentially a rural state. The establishment of good roads and county hospitals is making it possible to have fewer well trained men take care of the medical needs of more people.

(To be continued)

THE DALLAS SESSION

Phi Chi Medical Fraternity Banquet

There will be a banquet for the Phi Chi Medical Fraternity on the Roof Garden of the Jefferson Hotel at 6:30 p. m, Thursday, April 22, under the auspices of the Xi Chapter of Baylor Medical College. Dr. J. O. McReynolds will be the toastmaster, and Dr. T. B. Pearson of Nicholasville, Ky., grand secretary of the Phi Chi fraternity, is expected to be present.

A Phi Chi registration booth will be located near the Registration Bureau in the Automobile-Manufacturers' Building, Fair Park. "Open house" will be maintained at the Chapter House of Xi, 3609 Gaston Avenue, Dallas.

Alpha Omega Alpha Dinner

A dinner for all members of the Alpha Omega Alpha Honorary Fraternity and for their friends will be held at the Baker Hotel, Dallas, at 6:30 p. m., Wednesday, April 21. After the dinner there will be a session of the Tenth International Council of the fraternity.

Practical Demonstrations of Periodic Health Examinations

A practical demonstration of the method of conducting periodic examinations of the apparently healthy will be given at 8:30 a. m. and 4:30 p. m. on Monday and Tuesday, April 19 and 20, in Hall F of the Automobile-Manufacturers' Building, Fair Park. These will be conducted by Professor Carter and other members of the Department of Medicine of Baylor University College of Medicine.

These demonstrations have been arranged for the members of the American Medical Association.

one for four years and one for six years. No one can be appointed to the board who has received a degree in any of the healing arts, or who is a trustee, director, officer or employee of any hospital. The new law provides that every person desiring "to take an examination" to be admitted to practice any branch of the healing art must show by written examination by this board that he has a comprehensive knowledge of anatomy, physiology, hygiene, pathology and diagnosis. To be admitted to the examinations, he must satisfy the board that he is a person of good moral character and that he was a graduate of a high school or possessed equivalent educational qualifications before he began the study of the healing art. The board conceives its function as a board of elimination, a coarse seive through which applicants for a license to practice the healing art must first pass, with consequent elimination of the obviously unfit. The new law provides that a certificate from the state board of healing arts is prerequisite to examination by the Connecticut medical examining board, the Connecticut homeopathic medical examining board, the Connecticut eclectic medical examining board, the state board of osteopathic registration and examination, the state board of chiropractic examiners, or the state board of naturopathic examiners. It is too early to say whether or not any significance attaches to the fact that thus far, with I believe one exception, all the applicants before the board of healing arts have been graduates of regular schools of medicine. One would have supposed that a number of graduates of other schools would have appeared for examination before this time. It may be that the high school education requirement is a little too much of a hurdle for some.

Fraudulent Medical Diplomas, and How Some Holders Secured Licenses

Frederick C. Waite, Ph.D., Cleveland: It is only the choice, the valuable, the desirable things that are counterfeited. With the great improvement in medical education in the twenty-five years just past, the genuine medical diploma has come to be in the public mind one of the most highly prized professional hall marks of our modern life. Above everything else, the power to revoke a license should be vested in the board. The law should provide, in cases of guilt, for degrees of punishment. With such discretionary powers, there is no necessity of making provision for future restoration of license.

Annual Registration of Physicians: Reregistration in Iowa

Dr. Don M. Griswold, Des Moines, Iowa: In 1906 there were about 5,000 persons practicing medicine in the state of Iowa, as nearly as can be estimated. Shortly after this date the work of the committee of medical education of the American Medical Association began to be felt. The supply of poorly trained physicians was being shut off at its source. It can be said with truth and justice and should be proclaimed from the housetops that the medical profession has "cleaned its own kitchen." As a result of the tireless and unceasing work of its board members, who were guided and directed by the Council on Medical Education of the American Medical Association, this important work has been done. The barriers at the front door of our profession are sufficiently high and sufficiently strong to withstand any assault. This state of affairs gives us time to look about for the other avenues of entrance than the "front door." Every fraudulently used license that is not meaningless or an outright forgery has been issued honestly to some one. These licenses that have no termination go on serving a purpose for some fraud, years after the man who earned it was sleeping in his grave. The license of a dead physician may be innocently sold as part of the assets of an estate. To frustrate this entrance from the "side door," several states, including Iowa, require an annual reregistration of the license to practice medicine. The holder of each license is addressed annually and asked whether he wishes to use his license during the coming year. If he does, he pins his check for one dollar to the enclosed card and returns it to the office of the board. If the licensee has died, retired, moved away or for any other reason does not receive the notice, the postmaster, family or friends notify the board and proper record is made of the fact.

DISCUSSION

Dr. T. J. Crowe, Dallas, Texas: Men are going about the country, or were, using old diplomas and using old license certificates, simply taking out the name and inserting the name of another man, many of whom had been dead twenty years. Texas has tried to overcome that thing by issuing its license certificate on bank note paper, so that it cannot be changed or erased without detection. Dr. Waite's work, I think, was well done, but I think he made rather a doubtful use of it in publishing to the world that the state boards of this country are of doubtful caliber.

Dr. James Stewart, Jefferson City, Mo.: Dr. Waite's paper was one of the most interesting papers that I have heard. I have heard a lot about diploma mills. I want to add one more mill, and that is the state certificate mill. I want to ask you how can all of these men who have graduated from these inferior schools and from schools of no standing whatsoever, without any premedical education, come before state boards of health and get state certificates to practice medicine? There have been numbers of men in Missouri, and I guess elsewhere, who have paid all the way from $250 to $2,800 for state certificates to practice medicine.

Dr. David Strickler, Denver: I think it is very desirable that the annual registration should be carried out in Colorado. We have no data in our office to tell how many of these frauds are in the state at the present time. I should like to know whether in annual registration returns you simply give the name and address of the physician or whether you give any information as to the school he graduated from and when. The conditions on which he was licensed, it seems to me, would be good information.

Dr. Henry W. Briggs, Wilmington, Del.: The function of a state examining board is just as much to look after the men after they have been licensed as to license them, and, if necessary, to take their license away from them when they become unworthy. In the matter of interstate endorsement: If a man comes from a state the standard of which is equal to our own, and comes with proper training, premedical and medical; if he has had one year's internship in an accredited hospital, and has the recommendation of his own state board, signed by one of the officials, under seal, we will endorse the license without inquiry as to whether that particular state will take one of our men. In my state we have compulsory annual registration and it works very much to our advantage. Every physician in our state, in lieu of a state tax on any real estate which he might own, must pay to the state $10 for the privilege of practicing in that state that year. After the first day of June of each year, nobody is licensed in that state until he renews his license and registers with the clerk of the county in which he happens to live.

Dr. H. M. Platter, Columbus, Ohio: Class C schools have not been on the accredited list of the Ohio state board. Two years ago we interrupted a diploma mill at Marietta. We have to be constantly on the alert to prevent the certificates of physicians who have died being sold, to a new physician who never saw a medical college. We have our troubles in examinations. Last year we threw two out for cheating. Not one of us is so smart that he cannot be imposed on.

Dr. C. C. Pierce, Chicago: There is not at the present time nor has there ever been a graduate of any other than a class A school in the commissioned corps of the Public Health Service. After the war, the Public Health Service was authorized to recruit a reserve corps. We took in about 1,500, practically all of them ex-service men. We enrolled these men without examination, on the strength of their army service and the credentials they presented. I know of one instance in which a graduate of the St. Louis College of Physicians and Surgeons was accepted to do laboratory work in a Veterans' Bureau hospital. That man, however, is no longer connected with the service.

Dr. Harold L. Rypins, Albany, N. Y.: In the first place, registration must be annual. In the second place, it must raise enough money so that the administrator will have funds to investigate illegal practitioners. In the third place, the statute must be worded so that a man not having a license and not on the annual printed list will be automatically proved an unlicensed practitioner. In the fourth place, there must be permanent, efficient machinery for carrying out attacks against those who do not appear on the annual registration list.

Dr. I. D. Metzger, Pittsburgh: The state of Pennsylvania last year passed a reregistration act which made necessary the tabulation of all the persons in the state licensed for the practice of the healing art. That includes not only physicians but also osteopaths, druggists and therapeutists. It also includes chiropodists and physiotherapists. There are some 13,000 in the state of Pennsylvania. A fee of $1 in charged.

Dr. Augustus Downing, Albany, N. Y.: The members of every profession in the state of New York, including architects and engineers, have to register annually. This annual registration acts as a drag-net, and sooner or later every illegal practitioner is caught.

Dr. Robert L. Rowley, Hartford, Conn.: We do not have an eclectic examining board in Connecticut at this time, which is due not to the fact that the law has been changed but to the fact that the governor has been unable to find enough members in the eclectic medical society to fill the appointments on the board. I think our troubles are at an end for a time.

Frederick C. Waite, Ph.D., Cleveland: You would think I had disclosed something here. Anybody who has subscribed for The Journal of the American Medical Association and has bought the directory has all the figures I have given. I have simply compiled them.

Dr. Don M. Griswold, Des Moines, Iowa: We send to the county medical society only the names and addresses and ask for corrections on that list. As to the funds for financing this measure, the money collected should be kept in a separate fund for carrying out the purposes of the act that was effective in collecting it, or else it should be put back into the general funds of the state, with the hope that a comparable sum will be made available to the department for carrying out the purposes of the act. Our state is essentially a rural state. The establishment of good roads and county hospitals is making it possible to have fewer well trained men take care of the medical needs of more people.

(To be continued)

THE DALLAS SESSION

Phi Chi Medical Fraternity Banquet

There will be a banquet for the Phi Chi Medical Fraternity on the Roof Garden of the Jefferson Hotel at 6:30 p. m., Thursday, April 22, under the auspices of the Xi Chapter of Baylor Medical College. Dr. J. O. McReynolds will be the toastmaster, and Dr. T. B. Pearson of Nicholasville, Ky., grand secretary of the Phi Chi fraternity, is expected to be present.

A Phi Chi registration booth will be located near the Registration Bureau in the Automobile-Manufacturers' Building, Fair Park. "Open house" will be maintained at the Chapter House of Xi, 3609 Gaston Avenue, Dallas.

Alpha Omega Alpha Dinner

A dinner for all members of the Alpha Omega Alpha Honorary Fraternity and for their friends will be held at the Baker Hotel, Dallas, at 6:30 p. m., Wednesday, April 21. After the dinner there will be a session of the Tenth International Council of the fraternity.

Practical Demonstrations of Periodic Health Examinations

A practical demonstration of the method of conducting periodic examinations of the apparently healthy will be given at 8:30 a. m. and 4:30 p. m. on Monday and Tuesday, April 19 and 20, in Hall F of the Automobile-Manufacturers' Building, Fair Park. These will be conducted by Professor Carter and other members of the Department of Medicine of Baylor University College of Medicine.

These demonstrations have been arranged for the members of the American Medical Association.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Health at Birmingham.—Telegraphic reports to the department of commerce from seventy cities with a total population of 29,000,000 for the week ending March 13 indicate that the highest mortality rate (27.4) is for Birmingham, while the rate for the group as a whole was 17.7. The mortality rate for Birmingham in the corresponding week of last year was 21.5, and for the group of cities as a whole, 15.

ARIZONA

State Medical Meeting.—The annual meeting of the Arizona State Medical Association will be held at Globe, April 26-28, under the presidency of Dr. Roderick D. Kennedy, Globe, and with the Gila County Medical Society acting as hosts; among the speakers will be Dr. William F. Braasch, Mayo Clinic, Rochester, Minn., "The Recognition and Treatment of Urinary Infection"; Dr. Charles C. Browning, Los Angeles, "The Influence of Focal Infection in Relation to Tuberculosis"; Dr. George Dock, Pasadena, Calif., "Iron Therapy; New Light on an Old Subject"; Dr. James F. Cooper, American Birth Control League, New York, "Contraceptive Technic"; Dr. Ancil E. Martin, Phoenix, "Tularemia"; Dr. John W. Flinn, Prescott, "The Pathology of Bone and Joint Tuberculosis," and Dr. Will G. Shultz, Tucson, "Ureteral Calculi." There will be a general meeting in the evening open to the public. Dr. George A. Bridge, Bisbee, is the president-elect.

CALIFORNIA

Society News.—The fifth annual meeting of the Pacific Coast Association of Anesthetists will be held in Oakland, April 28-May 1, with headquarters at the Hotel Oakland.——The April 1 meeting of the Los Angeles County Medical Association was a joint meeting with the pediatric society; the subjects discussed were "Measles," "Scarlet Fever," "Diphtheria" and "Intradermal Vaccination for Smallpox."

Licenses Revoked and Suspended.—At the regular meeting of the board of medical examiners of the state of California, Los Angeles, March 9-11, the license to practice as a physician and surgeon in the state of the following named persons was revoked:

Dr. William A. Strole, 323 West Sixth Street, Los Angeles; Dr. Robert W. Renwick, 5975 Moneta Avenue, Los Angeles; Dr. Charles K. Holsman, 1134 Market Street, San Francisco; Dr. Herbert E. Bogue, 11401 Santa Monica Boulevard, Sawtelle, Los Angeles County.

The licenses of the following physicians were suspended:

Dr. Ludwig H. Wolfsen, 848 Tenth Street, Modesto, for a period of one year; Dr. Frederick K. Lord, Ceres, for a period of one year. The period of probation of Dr. Olaf A. Kvello, Hemet, was continued for two years, with the further condition that he surrender his federal narcotic permit and his federal alcohol permit, both in his own behalf and on behalf of the hospital which he conducts, and that he neither apply for nor receive during the coming two years a federal narcotic permit or a federal alcohol permit.

CONNECTICUT

Amedeo Pasciuta Fined.—Amedeo Pasciuta, Meriden, was found guilty of practicing medicine without a license, in the New Haven Superior Court recently, and fined $100. Pasciuta claimed to be a graduate of the St. Louis College of Physicians and Surgeons in 1923; he was the only person passed by the Connecticut Eclectic Examining Board in 1925. The state department of health, however, declined to license Pasciuta on the ground that he was not graduated from an eclectic school.

DISTRICT OF COLUMBIA

The Kober Lecture.—Dr. Oscar B. Hunter, assistant dean and professor of bacteriology and pathology, George Washington University Medical School, was chosen by the Medical Society of the District of Columbia to deliver the lecture of the Kober Foundation at Gaston Hall in the Healy Building of Georgetown University, March 28. The subject of the lecture was "The Pathological Elements Underlying Myocardial Degeneration, Cardiac Failure and Cardiac Rupture Resulting from Acute and Chronic Occlusion of the Coronary Vessels" (illustrated with lantern slides).

GEORGIA

Personal.—Dr. James D. Manget, Atlanta, has been elected president of the staff of the Georgia Baptist Hospital.——Dr. George T. Olmstead has been elected medical director of the Savannah Hospital, to succeed Dr. Robert V. Martin.——Dr. J. E. Lester, Acworth, has been appointed health officer of Cobb County.——Dr. D. H. Monroe has been elected health officer of Cartersville, and also district health commissioner for Bartow County.——Dr. J. W. Wallace, Thomasville, has taken up his duties as county health officer of Thomas County.——Dr. John M. T. Finney, Baltimore, recently, was the guest of the Richmond County Medical Society, Augusta.

ILLINOIS

Lectures on Mental Hygiene.—Seven lectures will be given in Springfield between March 26 and May 7, by the Illinois Society for Mental Hygiene under the auspices of the Springfield Council of Social Agencies; among the lecturers will be Dr. H. Douglas Singer and Dr. Paul L. Schroeder, April 9, and April 29, on "Behavior Difficulties of Adolescents and Adults," and "Behavior Difficulties of Young Children," respectively.

Chicago

Informal Reception at Rush.—The faculty and student council of Rush Medical College of the University of Chicago held an informal reception in the library of the new Rawson Building, April 9, at 8:15; Dr. Frank Billings, for many years dean of the faculty of Rush College, gave an address.

Annual Dental Clinic.—The Chicago College of Dental Surgery will celebrate its forty-third anniversary with a "Home Coming Clinic," April 12-13, at the school, 1747 West Harrison Street.; the classes of 1886, 1891, 1896 and 1901 will be the guests of the college and the Alumni Association. There will be a banquet, Monday evening, April 12, at the La Salle Hotel.

Society News.—A dinner was held at the Hamilton Club, March 24, by members of the Chicago Medical Society in honor of Dr. Edward Starr Judd, Rochester, Minn., who addressed the society on "Cholecystitis with Consideration of Some of the Associated Problems."——Dr. Carl A. Hedblom will address the Chicago Tuberculosis Society, April 8, on chest surgery.——Prof. Robert H. Gault, Ph.D., of Northwestern University, Evanston, was the guest of honor of the Chicago Laryngological and Otological Society, April 5.——Dr. Solomon Strouse and Chi Che Wang, Ph.D., addressed the Chicago Society of Internal Medicine, March 22, on "Effect of Mechanical Work on Heat Production in Obese Individuals."——The dental operating room and the oral surgery unit in the new Passavant Memorial Hospital will be dedicated as a memorial to George H. Cushing, D.D.S., who founded the Chicago Dental Society and the Illinois Dental Society, and was one of the organizers of the American Dental Association.——The April 7 meeting of the Chicago Medical Society was a joint meeting with the South Branch; there was a symposium on "The Decompensating Heart," in which Drs. Isaac A. Abt, Joseph B. De Lee, Charles L. Mix and James Monahan took part.——The Chicago Roentgen Society will meet jointly with the Central Radiological Society of Illinois in Champaign, May 18, in addition to its regular meeting in May.——Dr. Arthur Steindler, professor of orthopedics, State University of Iowa College of Medicine, Iowa City, addressed the Chicago Orthopedic Society, April 9, on "Scoliosis."——Among others, Dr. Harry L. Parker, Mayo Clinic, Rochester, Minn., will address the Chicago Neurological Society at the Drake Hotel, April 15, on "Involvement of the Central Nervous System Secondary to Primary Carcinoma of the Lung."

INDIANA

Personal.—Dr. Lafayette Page, Indianapolis, has been elected president of the Indiana Academy of Ophthalmology and Otolaryngology; Dr. Louis D. Brose, Evansville, vice president, and Dr. Daniel S. Adams, Indianapolis, secretary-treasurer.——Dr. John E. Luzadder, Bloomington, has been appointed secretary of the Monroe County Board of Health.——Dr. Harold J. Norton has been appointed a member of the board of health of Columbus.

Another Package Library.—A package library service for the medical profession of Indiana has been proposed at the state university, which would be similar to that established in Wisconsin through the cooperation of the state medical society and the University of Wisconsin, and that of the American Medical Association. The classifications will probably be made by the librarian of the Indiana University School of Medicine, and will consist of reprints, clippings from medical journals and of addresses before medical societies. Physicians may communicate, says the *Indianapolis Medical Journal*, with Mrs. Edna Hatfield Edmonson of the extension division of the state university or with the librarian of the state medical school. When the service is fully established, packages may be obtained for two weeks on request, free of charge, except postage one way.

IOWA

Personal.—Dr. Anthony P. Donohoe has been elected president of the staff of Mercy Hospital, Davenport, and Dr. James R. Guthrie, president of the staff of St. Joseph's Mercy Hospital, Dubuque.——Dr. William M. Park, Indianola, celebrated his fiftieth anniversary in the practice of medicine, March 1.——Dr. Franklin C. Hull, Carlisle, celebrated the fiftieth anniversary of his graduation in medicine, February 16.——Dr. Alvin H. Hendrickson has been appointed county physician at Sioux City.

Society News.—Dr. Ernest Sachs, St. Louis, conducted a clinic on brain lesions at Des Moines, March 9, and in the evening addressed the Des Moines County Medical Society on "Brain Injuries"; April 13, Dr. Edward H. Skinner, Kansas City, will address the society on "The Recognition and Management of Malignancy of the Uterus"; Dr. Skinner will address the high school assembly on "Cancer" in the forenoon, a union meeting of various clubs at noon, and a group of nurses in the afternoon.——Dr. Charles J. Drueck, Chicago, addressed the Des Moines County Medical Society, Burlington, recently, on "Practical Points in Proctology."

KENTUCKY

Superintendents Transferred.—Dr. W. M. Elliott, superintendent of the Central State Hospital, Lakeland, has been transferred to the superintendency of the Feeble Minded Institute at Frankfort, and Dr. Wallis W. Durham, superintendent of the Western State Hospital, Hopkinsville, has been appointed superintendent of the Lakeland Hospital. Dr. Elliott succeeds Dr. Thomas L. Taylor at Frankfort, who resigned to accept a hospital position in Hawaii.

MARYLAND

Exchange Professors.—Arrangements have been completed for an exchange of professors between the Johns Hopkins School of Hygiene and Public Health and the London School of Hygiene and Tropical Medicine. Robert W. Hegner, Ph.D., professor of protozoology at Johns Hopkins University School of Hygiene and Public Health, left for London, March 31. Dr. John G. Thomson, director of protozoology at the London institution, arrived in New York, March 26, and is expected in Baltimore within the next few days. The exchange of professors, which will cover a period of about six months, is the result of an arrangement between Dr. Andrew Balfour, director of the London school, and Dr. William H. Welch, director of Johns Hopkins University School of Hygeine and Public Health, for furthering an exchange of ideas and comparing the personnel and methods of the two institutions. This is the second exchange that has been made by the Johns Hopkins School of Hygiene and Public Health. The first was effected two years ago between the Hopkins department of medical zoology and the Peking Union Medical College of China, when William W. Cort, Ph.D., the Johns Hopkins University School of Hygiene and Public Health specialist in helminthology, was exchange professor.

MASSACHUSETTS

Personal.—Dr. Harry H. Nevers, for eighteen years city bacteriologist of Lawrence, has resigned.——Dr. S. Burt Wolbach, professor of pathologic anatomy, Harvard University Medical School, Boston, addressed the scientific staff of the Rockefeller Institute for Medical Research, New York, March 26, on "A Résumé of Rickettsia Research."——Dr. Frederic J. Cotton gave a luncheon at his home recently in honor of Dr. Dean Lewis of Johns Hopkins University Medical School, Baltimore, which was attended by a number of prominent surgeons of Boston.

Boston City Hospital.—A new maternity building for the Boston City Hospital will be erected at Concord and Albany streets, for which $750,000 has been appropriated; $250,000 has been appropriated according to the *Boston Medical and Surgical Journal*, for a research laboratory for the study of streptococcic infections. There has been erected a new outpatient building and a new roentgen-ray laboratory, and plans for other additions have been approved. During the year ending Jan. 31, 1925, more than 21,000 patients were admitted to the hospital and 210,173 treated in the outpatient departments. The total expenditures noted in the annual report amounted to $1,686,737.04, while the payments for services rendered to patients, including receipts from the state and cities and towns, amounted to $173,503.83. All departments for the care of patients, it appears, have been overcrowded, and larger facilities are needed.

MICHIGAN

Faculty Promotions at the University.—The board of regents of the University of Michigan, Ann Arbor, made the following promotions in the faculty of the medical school, February 25; Elizabeth C. Crosby, Ph.D., to be assistant professor of anatomy; Henry C. Eckstein, Ph.D., to be assistant professor of physiologic chemistry; Albert G. Young, Ph.D., to be assistant professor of pharmacology, and Daniel A. McGinty, Ph.D., Alrick B. Hertzman, Ph.D., and Detlev W. Bronk, M.S., to be assistant professors of physiology.

Society News.—Dr. John Phillips, Cleveland, addressed the Wayne County Medical Society, Detroit, March 9, on "Angina Pectoris"; Dr. George W. Crile, Cleveland, addressed the society, March 15.——Dr. William E. Shackelton addressed the Kent County Medical Society, Grand Rapids, March 24, on "Hernia of the Stomach Through the Diaphragm," and Dr. Augustus W. Crane, both of Kalamazoo, on "Acute Intestinal Obstruction."——Dr. Philip H. Kreuscher, Chicago, addressed the Wayne County Medical Society, March 23, on "Backache"; the meeting of the society, March 30, was in charge of the entertainment committee.

MINNESOTA

Society News.—Dr. Smiley Blanton addressed the Minnesota Academy of Medicine, March 10, on "Some New Applications of the Principles of Psychological Medicine."——Dr. Jacob Harry Bendes, Oak Terrace, was elected president of the Minnesota Sanatorium Association at the annual meeting; Dr. William D. Beadie, Cannon Falls, a vice president, and Beatrice E. Lindberg, St. Paul, secretary.

Lowest Birth Rate in Fifteen Years.—The secretary of the state board of health is said to have reported, March 24, that the birth rate in 1925 in Minnesota was the lowest in fifteen years, 20.9 per thousand of population. There has been a steady decline in the birth rate in the state since 1921, when it was 24; in 1910, however, the birth rate was 20.1, and in 1915 was the highest in recent years, 24.6.

MISSOURI

Personal.—Dr. H. I. Spector, St. Louis, announces that he has resigned his position as tuberculosis controller of St. Louis and hereafter will devote all his time to private practice.——Dr. Robert E. Crabtree has been appointed deputy health commissioner for Bates County.

Report on Medical Schools.—The report filed in the supreme court, March 6, by Special Commissioner Edwin J. Bean, recommended that the charters of the Kansas City College of Medicine and Surgery and the St. Louis College of Physicians and Surgeons be revoked; both of these schools have been repeatedly mentioned in the exposure of the medical diploma mills.

NEW HAMPSHIRE

New Hampshire Surgical Club.—The twenty-eighth semiannual meeting of this organization will be held at Nashua, Tuesday, April 27. The operative clinic will be held at St. Joseph's Hospital, beginning at 10 a. m.; in the afternoon there will be a discussion of the morning's work and the presentation of papers at the Nurses' Home of the Memorial Hospital. There are 200 regular members of the New Hampshire Surgical Club, all of whom, as well as the honorary members in other states, will be cordially welcome at this meeting.

NEW YORK

Rabies in Dogs.—There were 144 cases of rabies in dogs in New York in 1925, according to the Department of Farms and Markets, and ninety-seven of them occurred in Westchester county; thirteen rabid dogs were discovered in Nassau county at Hempstead in the five weeks ending February 26, and that was the same number, it is reported, which had been found in Hempstead in the previous nine months.

Resignations at State Hospitals.—The February number of the *State Hospital Quarterly* notes the resignations of the following physicians at the state hospital indicated:

Dr. Joseph L. Abramson, assistant physician in Kings Park State Hospital.
Dr. Theodore Gallup, assistant physician in Kings Park State Hospital.
Dr. Paul M. Jerrell, assistant physician in Gowanda State Homeopathic Hospital.
Dr. John W. Ross, assistant physician in Hudson River State Hospital.
Dr. Emanuel Allen Schiffman, assistant physician in St. Lawrence State Hospital.
Dr. Kathleen M. White, assistant physician in St. Lawrence State Hospital.

State Medical Election.—At the annual meeting of the Medical Society of the State of New York, New York, March 29-April 1, Dr. George M. Fisher, Utica, was elected president; Dr. James E. Sadlier, Poughkeepsie, president-elect; Drs. John E. Jennings, Brooklyn, and George M. Cady, Oswego, vice presidents; Dr. Daniel S. Dougherty, New York, secretary, and Dr. Charles Gordon Heyd, New York, treasurer. Dr. Edward Eliot Harris, New York, was elected speaker of the House; Dr. Harry R. Trick, Buffalo, vice speaker, and Drs. William H. Ross, Brentwood, Nathan B. Van Etten, New York, and Frederick H. Flaherty, Syracuse, trustees.

New York City

University News.—Columbia University is offering a five weeks course in internal medicine for qualified graduates in medicine from June 14 to July 16, and registration for this course closes May 22; it will be a practical course in the wards and laboratories of the Presbyterian Hospital. The fee is $100.

Dr. Landis Cited.—The state board of medical examiners summoned Dr. Leonard Lincoln Landis, New York, March 29, it is reported, to appear before the board in Albany, April 10, to show cause why his license to practice should not be revoked. The evidence on which the state board's summons was based is said to have been obtained recently.

Gifts to Medical School.—Chancellor Brown announces that, during the current year, gifts amounting to $29,000 have been made to New York University and Bellevue Hospital Medical College for use in various departments. R. T. Crane, Jr., Chicago, for the second year, has given $4,000 for the study of anaphylaxis, which is being carried on under Holmes C. Jackson, Ph.D., by Dr. A. Bret Ratner of the department of children's diseases; $10,000 was given to the school, anonymously, through Dr. John M. Wheeler for experimental work in ophthalmology, and $10,000 was given by Mr. Littauer for studies in the prevention and treatment of pneumonia.

OHIO

Personal.—Dr. Lyman A. Adair, Wooster, has been appointed acting county health officer to succeed Dr. Clarence D. Barrett, who resigned to become health officer at Mansfield.——Dr. Ralph W. Holmes Chillicothe, was elected secretary of the Ohio Society for Crippled Children at the recent annual meeting of the society in Columbus.——Dr. Stanley E. Dorst, Cleveland, has been appointed assistant professor of internal medicine at the University of Cincinnati College of Medicine.——Dr. Roger G. Perkins has been elected chairman of the Cleveland Health Council.——Joseph Webb has been elected chief surgeon of the Springfield City Hospital.——Dr. James B. Poling has been reelected health commissioner of Lima for a five year period; Dr. Poling completed, April 1, the unexpired term of the late Dr. Arthur L. Jones.

State Medical Meeting.—The eightieth annual meeting of the Ohio State Medical Association will be held at Toledo, May 11-13, with headquarters at the Secor Hotel. The first general session will be combined with the first session of the house of delegates, May 11, 9:30 a. m.; the president Dr. Clarence D. Selby, and the president-elect, Dr. Leora G. Bowers, will deliver their addresses, May 11, at 8 p. m., when there will be an informal reception and dance. In addition to the Ohio physicians on the scientific program, addresses will be given by Dr. Foster Kennedy, Cornell University Medical College, New York, on "The Medical Expert in the Courts"; Dr. Stewart R. Roberts, Atlanta, Ga, "Functional Pressure Versus Structural Sclerosis"; Dr. Frank B. Granger, Boston, "Medical Diathermy"; Dr. Gordon B. New, Mayo Clinic, Rochester, Minn., "Newer Methods and Procedures in Plastic Surgery," and Dr. George W. Hall, Chicago, "Mental Disturbances as Observed in a General Hospital." The clinics to be held at various hospitals, May 10, will be announced on bulletin boards of hotels, May 9. The sixth annual tournament of the Ohio Medical Golfing Association will be at the Inverness Club, May 10.

OKLAHOMA

Illegal Practitioner Fined.—The *Journal of the Oklahoma State Medical Association* notes that William McNabb was recently arrested in Enid for practicing medicine without a license, and was fined $150 and costs.

Crippled Children's Clinics.—Under the auspices of the Oklahoma Society for the Care of Crippled Children, Drs. Samuel R. Cunningham, Oklahoma City, and William Patton Fite, Muskogee, held clinics at Wagoner and Talequah, February 26-27, for the crippled children of Wagoner and Cherokee counties.

Osteopath Charged with Manslaughter.—Albert L. Black, an osteopath of Guthrie, has been charged with manslaughter, it is reported, following the death of an 8 year old boy during an operation for removal of his tonsils. The trial involves the construction of the law to decide whether an osteopath is allowed to perform tonsillectomies in Oklahoma.

PENNSYLVANIA

Society News.—Dr. Arthur C. Morgan, professor of applied therapeutics, Temple University School of Medicine, Philadelphia, addressed the Northampton County Medical Society, Easton, March 19, on "Treatment of Acute Cardiac Tragedies."——The annual meeting and election of officers of the Allegheny County Medical Society will be held at the William Penn Hotel, Pittsburgh, April 15.——Dr. Dean Lewis, chief surgeon, Johns Hopkins Hospital, Baltimore, addressed the Westmoreland County Medical Society, Greensboro, April 6, on "The Treatment of Fractures and Their Complications."

Philadelphia

Funds for Research Bureau.—The late George S. Cox, who left an estate of several million dollars, provided that within ten years after the death of his widow, his real and personal property should be transferred to a fund to establish a research bureau whose object will be to discover a cure for diabetes and to pursue any other line of medical research that the director of the bureau may think best. Dr. Levi J. Hammond, an executor and trustee under the will, is appointed director of the bureau with full power to appoint his successor, either by personal appointment or by will. The successive directors are to have the same power to appoint their successors and of managing the bureau. Dr. Hammond has been connected with the Methodist Episcopal Hospital for about thirty years; he is now chief of staff.

Philadelphia's Oldest Hospital.—A new outpatient department is being constructed at the Pennsylvania Hospital, Eighth and Spruce streets. The new building will be on the site of the old "West Picture House," which was erected in 1818 to house the painting by Benjamin West of "Christ Healing the Sick" and which later became the home of the Pennsylvania Historical Society; it probably will be completed by the end of 1926, which will be the one hundred and seventy-fifth anniversary of the founding of this hospital. John Small, said to have been the first outpatient treated in America, was treated at the Pennsylvania Hospital, Dec. 13, 1752; in the records of 1753, Benjamin Franklin wrote that "several outpatients have received the advice of the physicians and the use of the medicine received from London." The outpatient department since then has grown, until last year 58,673 patients were treated. The new outpatient department will be four stories high, and provide almost five times as much room as the department now occupies.

SOUTH DAKOTA

Rush Reunion.—Rush Medical College alumni of South Dakota are requested to meet in reunion at Aberdeen, May 20, during the state medical association meeting; Dr. Rollin T. Woodyatt, Chicago, will speak on "The New Rush."

State Medical Meeting.—The forty-fifth annual meeting of the South Dakota State Medical Association will be held in Aberdeen, May 19-20, under the presidency of Dr. William R. Ball, Mitchell. Among the visiting speakers will be Drs. Vincent J. O'Conor, Chicago (urology); Benjamin F. Lounsbury, Chicago (surgical clinic); Donald A. Nicholson, Seattle (traumatic neuroses); Casper W. Sharples, Seattle (diverticulitis of sigmoid); William R. Murray, Minneapolis (clinic—acute external diseases of the eye); Dr. Frederick Tice, Chicago (medical clinic); Rollin T. Woodyatt, Chicago (diabetic clinic); Maximilian Kern, Chicago (endocrine gland clinic), and Dr. Merrill M. Myers, Des Moines (heart clinic). The meeting will be held at the Orpheum theater. There will be an entertainment at the Country Club in the evening, but no formal banquet.

WISCONSIN

Medical Examiners Meeting.—At the January meeting of the Wisconsin State Board of Medical Examiners, the board voted to raise the endorsement fee from $2 to $10, and to refund $35 on reciprocity fees and $15 on examination fees, when the credentials were unsatisfactory. Two applicants were refused the privilege of writing the January examination, one because his foreign credentials were unsatisfactory, the other because he had only one year of premedical work; two applicants for reciprocity were refused a license because the board did not recognize their schools; namely, the Chicago Medical School and the St. Louis College of Physicians and Surgeons. In the future, no applicant will be permitted to write the examination until he has first satisfied the requirements of the basic science board in accordance with a recent law.

Society News.—Dr. Stanley J. Seeger addressed the Milwaukee Neuropsychiatric Society, March 25, on "Some Impressions of Neurologic Surgery in London."——Dr. Erwin R. Schmidt, professor of surgery, University of Wisconsin Medical School, Madison, addressed the Milwaukee Academy of Medicine, February 23, on "Pituitary Tumors" with report of an unusual case.——Dr. Arthur J. McCarey addressed the Green Bay Academy of Medicine, February 10, on "Physical Examinations."——Dr. Harold E. Marsh addressed the Dane County Medical Society, Madison, February 17, on "Use of Novasurol in Treatment of Edemas."——The Milwaukee County Medical Society devoted its February meeting to a review of the recent advances in the basic sciences bearing on clinical medicine by the full-time professors of Marquette University Medical School. Dr. Gideon Wells, professor of pathology, University of Chicago, will address the Milwaukee County Medical Society, April 9.——Dr. Damon A. Brown addressed the Racine County Medical Society, recently, on "Hexylresorcinol as a Urinary Antiseptic."——At an organization meeting, March 17, at the Milwaukee Children's Hospital, sixteen pediatricians became charter members of the Milwaukee Pediatric Society and elected Dr. Lorenzo Boorse president, Dr. Roy M. Greenthal vice president, and Dr. Mynie G. Peterman, secretary-treasurer.——The Medical Society of Milwaukee County adopted a new set of by-laws at the March meeting; a board of five directors henceforth will conduct the business of the society.

GENERAL

Reunion of Resident Physicians.—Former medical house officers and assistant resident physicians of the Peter Bent Brigham Hospital, Boston, will hold a dinner at the Hotel Adolphus, Dallas, Texas, April 21, at 6:30 p. m. Further information can be obtained from Dr. Henry A. Christian at the Hotel Adolphus after April 18.

Druggists May Sell Malt Tonic.—General L. C. Andrews, assistant secretary of the treasury, and in charge of prohibition enforcement, has granted permits to two well known manufacturers to sell to druggists only a "medicinal malt preparation" which may contain not "in excess of 4 per cent alcohol and must contain at least 25 per cent of solids." In making his announcement, General Andrews states that this new policy was adopted after thorough consideration of the question and will permit the restoration to the market of certain well known and established malt tonics. The manufacturers are required to accept responsibility for their distribution for legitimate purposes and to watch distribution closely and withdraw the product from any market where it appears that the tonic is being held for use as a beverage. General Andrews further states that this is practical and reasonable and is done for the purpose of making these tonics available to those who need them. A malt tonic containing 25 per cent of solids is by no stretch of the imagination a "beer," according to General Andrews. No physicians' permits are required to secure the product from druggists.

National Board of Medical Examiners.—During 1925, the examinations of the National Board of Medical Examiners were completed by 206 physicians, all of whom have been awarded the certificate of the board. There were in this number graduates of eighteen different medical schools, the greatest number from any one being from Harvard (thirty-eight), then Pennsylvania (twenty-six), then Rush (twenty-five), then Johns Hopkins (sixteen), and the least number, three, each from Creighton, Columbia, Illinois, Pittsburgh and Vermont. Examinations in parts I and II will be held, June 21-23, in all class A medical schools in the country where a sufficient number desires to take them. Dr. Walter L. Bierring has been appointed acting chief examiner of the Chicago Subsidiary Board, to succeed the late Dr. Albert C. Eycleshymer; seventeen candidates were examined by this board in January; all of them passed. The third annual meeting of the Associated Diplomates of the National Board will be in Dallas, Texas, during the session of the American Medical Association; the date and place will be definitely announced in the association's daily bulletin during the meeting.

New County Society Presidents.—The following physicians have recently been elected president of the county medical society indicated:

Dr. Otto C. Ahlers, Sherman, Texas, Grayson County Medical Society.
Dr. Alden Alguire, Belvidere, Ill., Boone County Medical Society (reelected).
Dr. John A. Ascher, Freeport, Ill., Stephenson County Medical Society.
Dr. Willet W. Binion, Benevolence, Ga., Randolph County Medical Society.
Dr. Claude M. Bloss, Okemah, Okla., Okfuskee County Medical Society.
Dr. Udonna C. Boon, Chickasha, Okla., Grady County Medical Society.
Dr. Alexander H. Bressler, Manhattan, Kan., Riley County Medical Society.
Dr. Joseph C. Bunten, Augusta, Kan., Butler County Medical Society.
Dr. Malcolm Campbell, Malvern, Iowa, Mills County Medical Association.
Dr. Jacob B. Cato, Hutsonville, Ill., Crawford County Medical Society.
Dr. William M. Cott, Okmulgee, Okla., Okmulgee County Medical Society.
Dr. George A. Clark, Scranton, Pa., Lackawanna County Medical Society.
Dr. Marcus L. Cone, Campbell, Mo., Dunklin County Medical Association.
Dr. James M. Dell, Gainesville, Fla., Alachua County Medical Association.
Dr. George R. Fox, Moreauville, La., Avoyelles County Medical Society.
Dr. Linwood M. Gable, Griffin, Ga., Spalding County Medical Association.
Dr. William P. Greening, Pauls Valley, Okla., Garvin County Medical Society.
Dr. Harry H. Hammel, Tecumseh, Mich., Lenawee County Medical Society.
Dr. Thomas J. Hickman, Lenoir City, Tenn., Loudon County Medical Society.
Dr. Jesse J. Hipes, Colgate, Okla., Coal County Medical Society.
Dr. Joseph W. Hope, Hampton, Va., Elizabeth City County Medical Association.
Dr. Leo W. Hornick, Johnstown, Pa., Cambria County Medical Society.
Dr. Harold L. Hurley, Jackson, Mich., Jackson County Medical Society.
Dr. John L. Jeffress, Ada, Okla., Pontotoc County Medical Society.
Dr. John W. Krohn, Joliet, Ill., Will-Grundy Counties Medical Society.
Dr. William H. Langston, Guyon, Okla., Texas County Medical Society.
Dr. James F. Leslie, Centralia, Wash., Lewis County Medical Society.
Dr. Lambert M. Lundmark, Ladysmith, Wis., Rusk County Medical Society.
Dr. Samuel T. McCabe, Johnsonburg, Pa., Elk County Medical Society.
Dr. Louis P. Munger, Hart, Mich., the Oceana County Medical Society.
Dr. George H. Parmenter, Beecher City, Ill., Effingham County Medical Society.
Dr. David P. Richardson, Union, Okla., Canadian County Medical Society.
Dr. John M. Ritter, Roosevelt, Okla., Kiowa County Medical Society.
Dr. Eugene C. Roseberry, Springfield, Mo., Greene County Medical Society.
Dr. George D. Ross, Liberty Hill, Texas, Williamson County Medical Society.
Dr. Samuel F. Sanders, Holdrege, Neb., Phelps County Medical Association.
Dr. Charles A. Shultz, Alvarado, Texas, Johnson County Medical Society.
Dr. Gust Sjolander, Midland, Mich., Midland County Medical Society.
Dr. Charles E. Slagle, Alliance, Neb., Box Butte County Medical Society.
Dr. Clinton F. Stofflet, Pen Argyl, Pa., Northampton County Medical Society.
Dr. William C. Ussery, Paris, Ky., Bourbon County Medical Society.
Dr. William A. Welton, Terra Alta, W. Va., Preston County Medical Society.
Dr. Thomas M. West, Fayetteville, N. C., Cumberland County Medical Society.

Senate Passes Lye Bill.—The bill to safeguard the distribution and sale of dangerous acids and alkalis was passed by the Senate, April 2. The measure is one which has for a long time been advocated by the medical profession, and provides for a uniform requirement to print the word "poison" in a conspicuous manner on containers of lye and other corrosive substances. The bill was originally introduced by Senator George Wharton Pepper of Pennsylvania; hearings were held by the Senate Committee on Interstate Commerce, when the reasons for the measure were fully presented. Senator James E. Watson of Indiana, chairman of the committee, has taken an active part in the passage of the bill; he wrote the report of the committee which summarized the reasons for the passage of the bill, and was in charge of the measure on the Senate floor. In a colloquy with Senator King of Utah, Senator Watson was able to overcome objections made to the bill. He said, in part:

> Perhaps a dozen states have enacted legislation, but there are many of the states that have not done so. There is where most of the difficulty occurs and there is where the children are poisoned. In response to

1,448 questionnaires sent out to physicians, it was learned that at one time there were 490 cases of this kind under treatment at once. Is there any reason in the world why the word "poison" should not be put on the label? That is all the bill provides. Many of the manufacturers do put the word "poison" on the label and put it on the bottle in legible characters. Some do not do so. Is there any reason why they should not be compelled to do it in order to protect child life and in order to put all of them in the market on equal terms?

It is simply a proposition to label as "poison" the ordinary lye that is used on floors in all the homes of the country. The evidence shows that the ordinary lye that is used on the floors in the homes of the country is sold at practically all grocery stores. A can or bottle of it is left out and a child gets hold of it, puts it in its mouth, and it results in a stricture of the esophagus. There were brought before the committee pictures of many children who were found in that condition and who were treated for the difficulty. The Senator from New York [Mr. Copeland] is perfectly familiar with the whole situation and was present when the hearings were held.

I will state that the proposed legislation is approved by the American Public Health Association, the American Child Health Association, the American Medical Association, and by the American Wholesale Grocers' Association. The interest of the latter organization in the bill is due to the fact that lye and similar substances are sold in all the retail grocery stores. The National Association of Retail Druggists is also in hearty sympathy with the proposed legislation.

FOREIGN

Instances of Injury from Roentgen Rays.—The *Schweizerische medizinische Wochenschrift* brings an appeal signed by the representatives of the five leading medical societies of Switzerland, asking for data in regard to injury from the roentgen rays, or from the apparatus or current, affecting patients, roentgenologists or attendants. They state that the honor of the medical and especially of the roentgenologic science demands this investigation. The fear of frightening the public must not deter as the public is already apprehensive beyond reason. A similar collective inquiry has been going on in Germany.

Practitioners' Week at Paris.—Extensive preparations have been made for the approaching Journées médicales, July 15-19, at Paris. The aim is to present in compact form the latest advances in diagnosis and treatment by practical demonstrations in hospitals and private clinics, arranged especially for the benefit of general practitioners. Each pays 50 francs on registration. The secretary is Dr. Dujarric de la Rivière, 18, rue de Verneuil, Paris. The annex exposition is in charge of M. J. Faure, 42, rue du Louvre, Paris. A few lectures by visiting authorities and numerous excursions are planned, as also the foundation of an international union of physicians, under the initiative of Dr. Decourt, president of the Union des syndicats médicaux de France—organizations for promoting the material interests of the profession. "Vaccination Against Tuberculosis" is to be described by Calmette at the first general meeting, which is to be opened by the president of the republic. Prof. F. Widal will preside thereafter.

Personal.—A volume of his collected works is to be presented to Prof. E. Tanzi, Florence, on his seventieth birthday, during the seventh congress of the Italian Society of Neurology at Turin in April.——A gold medal was presented to Prof. E. Gallemaerts as he reached the retiring age and left the chair of ophthalmology at Brussels. He is president of the Académie de médecine at Brussels.——Drs. José Carracido, professor of biologic chemistry, Madrid, and H. G. Greenish, professor of pharmacy, London, were recently elected corresponding members of the French Académie de médecine at Paris.——Prof. E. Hédon, Montpellier, who recently shared the Monaco prize for his pioneer work on the pancreas, was invited to lecture at the Liége medical school in March.——Dr. L. Severin Petersen has been placed in charge of the newly completed model gynecologic clinic at Bergen.——Dr. L. Fredericq, Liége, has been elected to fill the vacancy from the death of Bergonié in the list of corresponding members of the Académie des sciences at Paris.——Dr. and Col. Demolder presided in the medical section of the third international Congress on Aeronautics held recently at Brussels. Dr. Sand, Brussels, emphasized the importance of aeronautics from the epidemiologic and other points of view besides the military. Among the resolutions adopted was one urging standardization of parts, arrangements, etc., and one appealing to manufacturers to provide protection for the head of the aviator, as nearly all the accidents result from being flung against the posts and wall of the plane.——The semireclining marble statue of Professor Ramón y Cajal was recently unveiled in the Madrid park. It stands on a high rectangular pedestal in the center of a square pool fed by two fountains. The rear wall of the pool towers higher than the statue and bears bronze inscriptions and a bronze lifesize figure of Wisdom. Cajal shared with Golgi the Nobel prize in medicine in 1906.

Deaths in Other Countries

J. F. Gemmill, professor of natural history, University College, Dundee, by drowning, February 10.——**Henry Rayner**, former vice president of the Section of Psychology of the British Medical Association and coeditor of the *Journal of Mental Science*, February 8, aged 84.——**Dr. Sigmund Exner**, professor of physiology, Vienna, aged 80, a pioneer in the localization of function in the cortex, in the physiology of light and vision, and in applied acoustics. He was also the founder of the "Phonogrammarchiv."——**Dr. A. Felsenreich**, Vienna, formerly professor of gynecology and obstetrics, aged 78.——**Dr. Johannes Gad**, emeritus professor of physiology at the German University of Prague, aged 84. In 1887 he founded, with Exner, the *Zentralblatt für Physiologie*, and in 1893 he aided in organizing the work in experimental physiology at the Western Reserve University, Cleveland.——**Dr. Van der Vloet**, Brussels, former president of the Société belge de neurologie and founder of the St. Vincent Hospital at Antwerp.——**Dr. S. Patellani-Rosa**, for whom a chair on social eugenics was founded at the University of Milan, aged 57.——**Dr. E. Roos**, Freiburg, professor of internal medicine, aged 59.——**Dr. Castilho Marcondes**, Rio de Janeiro, the pioneer in bronchoscopy and esophagoscopy in Brazil, aged 36.——**Dr. E. Labat**, professor of obstetrics at Toulouse, with an extensive rural practice, contributor to the *Revue des deux mondes*, aged 72.——**Dr. J. Barsony**, professor of gynecology at Budapest, aged 66.——**Dr. K. Reifferscheidt**, professor of gynecology at Göttingen, aged 52.——**Mme. Kouindjy**, wife of Dr. P. Kouindjy, one of the first women physicians to practice in Paris.——**Dr. William Charles Sullivan**, medical superintendent of Broadmoor Criminal Lunatic Asylum, England, March 1, aged 56.

Government Services

Training Camps for Reserve Officers

Two fifteen-day training camps for medical reserve officers will be conducted at Carlisle Barracks, Pennsylvania, one, June 16-30, the other, July 4-18. According to the *Military Surgeon*, the arrangements made thus far provide for a schedule of training as follows: first corps area, Three Hundred and First Medical Regiment, July 4-18; second corps area, Three Hundred and Second, Three Hundred and Third and Three Hundred and Twenty-Third Medical regiments, June 14-30; and 100 officers, July 4-18; third corps area, Three Hundred and Forty-Third, Three Hundred and Sixty-Fourth and Three Hundred and Sixty-Fifth Medical regiments, June 16-30; fourth corps area, Three Hundred and Seventh Medical Regiment, June 16-30. The dates for the training of four medical regiments from the fifth corps area had not yet been selected. The first medical regiment of the regular army stationed at Carlisle Barracks, and several hundred R. O. T. C. students in camp during these periods will participate in the program of instruction for reserve officers. Officers assigned to a medical regiment will receive practical training in the operation of the various components of the regiment. Opportunities will be afforded to see many other recent developments in medical department organization.

Plans for Veterans' Bureau Hospitals

The director of the U. S. Veterans' Bureau is preparing plans for increasing the capacity of the new hospital at Great Lakes, Ill., by about 300 beds. It is proposed to start the work before the end of this fiscal year, and to expend on the project about $600,000. There will be three additional buildings for patients, an auditorium, a recreation building and an administration building.——Additional construction is contemplated for the veterans' hospital at Palo Alto, Calif., which will provide 300 additional beds, an administration building, and nurses and attendants' quarters at a cost of about $900,000. Among the larger projects for which preliminary plans are being made by the Veterans' Bureau, are a 300-bed neuropsychiatric hospital to be erected near Boston, at a cost of $1,350,000; a 250-bed tuberculosis hospital at Tucson, Ariz., to cost $1,000,000, and the replacement of the present hospital at Alexandria, La., at a cost of $1,400,000; additional officers' quarters will be erected at Aspinwall, Pa., and various other hospitals will be redecorated.

Foreign Letters

LONDON

(From Our Regular Correspondent)

March 13, 1926.

Endowment of Research at the London Hospital

It has been decided to devote the gift of $250,000 recently made to the London Hospital by an anonymous donor for the endowment of research into the causes of disease to paying salaries to research workers, "so that men and women may have more opportunity of taking up research as a life work and not simply as a stop-gap until some more lucrative branch of medicine is opened to them." The following dispositions have been made: 1. An annual scholarship in pathology of $500 a year, open to students from Oxford and Cambridge. Selection is made by examination. It is hoped by this scholarship for junior men to keep in touch with those who have a leaning toward research; it gives such men an opportunity of showing their capacity in laboratories attached to a great hospital. 2. A research fellowship of $2,000 per annum, tenable for three years. The candidate must be a whole-time worker and devote his time to a subject chosen for him. Such a man would act as an assistant to a senior research worker. 3. Two senior pathologists, who will receive the remainder of the money available, and who will devote their whole time to research work of their own choosing. The two pathologists appointed for this purpose are Dr. S. P. Bedson of the Lister Institute, and Dr. W. Howard Florey, at present John Lucas Walker Scholar of Cambridge University and working in America on the Rockefeller Foundation. The work will be carried out in the Hale and Dunn laboratories of the London Hospital, and the staff, material and equipment of these laboratories will be at the service of these workers.

Vital Statistics

The lowest birth rate in England and Wales for any fourth quarter of the year, apart from the war year of 1917, and the highest death rate since the influenza epidemic of 1918, were recorded during the last quarter of 1925. Quarterly returns for that period show that the births registered numbered 166,416, and were 4,511 below the number recorded in the corresponding quarter of 1924. The births registered in the quarter corresponded to an annual rate of 17.0 per thousand of the estimated population. The deaths numbered 126,274, 17,639 more than in the corresponding quarter of 1924. During 1925, 710,979 births and 473,006 deaths were registered. The natural increase of population by excess of births over deaths was therefore 237,973, as compared with an average annual increase in the preceding five years of 349,045. The number of persons married during the year was 590,332. The marriage rate in England and Wales during the year was 15.2 per thousand, the birth rate 18.3, and the death rate 12.2. The birth rate was the lowest recorded except during the war years 1917 and 1918; the death rate was equal to the rate recorded in 1924.

Distemper Research

The project of the *Field* to investigate the causes and cure of canine distemper—one of the most prevalent and most obscure diseases—by means of "the Field Distemper Fund" was reported previously in these columns. A report has now been issued which contains the following: "Our program has involved entirely new methods of research and progress. The source of distemper has been proved to be an invisible extremely minute organism or virus capable of passing through filters that will hold back all ordinary microbes or bacteria. Though this virus cannot yet be grown or propagated in a test tube, it has already been stored by appropriate methods for over a fortnight. Though our observers are not yet satisfied in every detail of their proof, they are already well on the way toward bestowing immunity from distemper on ferrets, animals which are particularly susceptible to the disease; and this, of course, is the first step toward giving immunity to dogs themselves."

Reduced Charges for Laboratory Tests

Considerable hostility in certain quarters has been aroused by the announcement that the Institute of Pathology at Charing Cross Hospital has inaugurated, at the suggestion of Dr. Fenton, dean of the medical school, a system of cut rates for every pathologic, bacteriologic or chemical examination performed, and this will be available to the middle classes, through the medium of physicians all over the country. The differences in prices are shown by the following comparisons:

	Charing Cross	Elsewhere
Wassermann blood reaction......	$1.25	$ 5.00 upward
Typhoid test	.60	2.50 upward
Blood counts for anemia.........	2.75	10.00
Tuberculosis test	.50	2.50 upward

Dr. Fenton says in the press: "Every single physician in the country can make use of our service. We have now been doing it for a fortnight. The first day we made 50 cents and yesterday we made $20. We do not intend to make money out of it. It is a purely philanthropic scheme. We must, of course, make it self-supporting and pay for the extra staff employed. Any money over and above that will be handed back to the public—either by actual donations to charity or in aiding other medical research work."

These low fees have aroused a good deal of criticism, and the powers of the general medical council and the censure of the British Medical Association have been hinted at. Sir William Smith, principal of the Royal Institute of Public Health, has written a letter of protest to the British Medical Association, challenging the right of a hospital to enter the commercial sphere. He also complains that circularizing physicians is a breach of the no advertising rule. The British Medical Association is considering the matter. On the other hand, the staff of the institute professes to be unconcerned and says that the British Medical Association can have nothing to do with the matter as it is not a private affair. "We do not make anything out of it, but we are doing a public service. Our scheme is to meet the needs of the middle class people who cannot afford the exorbitant fees charged for this class of work. We have to do it for hospital patients and so have room for doing it on a large scale. Physicians from all over the country send us blood to be examined. If they could not get this done so cheaply, their patients would have to go without the complete diagnosis."

Contamination of American Apples by Arsenic

In a previous letter (THE JOURNAL, Dec. 26, 1925, p. 2043) the finding of arsenic in American apples was reported. At a meeting of the Society of Public Analysts, Dr. H. E. Cox, M.Sc., read a paper on the presence of arsenic in apples. Attention was drawn to the matter by the occurrence of two cases of illness attributed to the spraying of apples with lead arsenate. He found that only five out of thirty-nine samples of Jonathan, King David and Newtown apples were free from arsenic, and eleven contained more than the statutory limit. The contamination is mainly, but not entirely, confined to the skin, arsenic having been found in the flesh of the fruit to the extent of about 3 per cent of that on the peel. It appears that rain does not remove all the arsenic. Washing under the tap, and even scrubbing, was found to leave appreciable amounts of arsenic on the fruit, presumably owing to combination of the arsenic with the proteins of the skin. A circular has been issued by the ministry of health urging local authorities to examine samples of apples likely to be so affected, and to withdraw from sale any consignments that appear to be injurious.

Professor A. R. Cushny

The death at the age of 60 of A. R. Cushny, M.D., LL.D., F.R.S., professor of materia medica and pharmacology in the University of Edinburgh, removes the foremost worker on pharmacology in this country. Born at Speymouth, Morayshire, he was educated in Aberdeen University and after graduation studied at Berne and Strasbourg, and at the latter university was appointed assistant to the professor of pharmacology in 1892-1893. In 1893 he was elected professor of pharmacology at the University of Michigan, Ann Arbor, which post he retained till 1905, when he returned to this country on his appointment to the chair of materia medica and pharmacology in the University of London. In 1918 he went to Edinburgh to succeed the late Sir Thomas Fraser. There he reformed his department, setting up an experimental laboratory and embarking on plans for the development of physiologic research in its relations to pharmacology. He was one of the first to analyze the mode of action of digitalis on the heart. He established the general principles by animal experiments and then, in collaboration with the late Sir James Mackenzie, made a study of the action of the drug in auricular fibrillation. This formed the basis of much of the work of Lewis and others. His researches on diuretics were of the first importance and he greatly advanced our knowledge of the mode of action of the kidney. He was an authority on the action of alcohol and served on several official inquiries as to the use of that substance as a beverage. His textbook "Pharmacology and Therapeutics and the Action of Drugs" reached its eighth edition and is generally recognized as the leading and most scientific work of the kind. It has had a great influence on the study of pharmacology both in this country and in America. His book on "The Secretion of Urine" was published in 1917. He also contributed much to English and American journals.

BELGIUM

(From Our Regular Correspondent)

Feb. 10, 1926.

New Medical Foundation of the University of Louvain

The Medical Foundation of the University of Louvain has decided to establish a new medical center on the Congo which will comprise (1) a hospital, principally for the natives, with two physicians in charge; (2) a research laboratory under the direction of a doctor of natural sciences, and (3) a training school for nurses. Later, a training school for medical assistants will be established. Since the cooperation of the resident missions is indispensable for the enlistment and the support of pupils, Kisantu has been chosen as the site for the new undertaking. The mission of Kisantu, which has been for thirty years in charge of Belgian Jesuits, has promised to aid the foundation. The association is certain of being able to send each year two or three young medical graduates to Kisantu to serve as assistants for one year.

The Dick Test in Belgium

Dr. Bessemans has reported his experiences with the intradermal Dick test carried out with the toxin of a hemolytic streptococcus in four schools comprising 620 children. The reactions were 31.8 per cent positive, 34.1 per cent protein reactions, and 68.2 per cent negative. The percentage of protein reactions seems to increase with the age of the subjects. The author, therefore, regards the influence of age on the receptivity for scarlet fever and on the hypersensitiveness to ordinary proteins as corresponding to similar phenomena when the Schick test is applied. He confirms the value of the Dick test. In Belgium alone, scarlet fever carries off from three to four hundred children every year.

Alastrim in the Congo Region

Dr. Van Hoof has published a study on alastrim in certain districts of the Belgian Congo. The author considers alastrim or milkpox as a blending of smallpox and chickenpox; but believes that it should be regarded as a distinct disease, for the following reasons: 1. In Stanley Pool, for many years, the author was able to observe cases of smallpox, alastrim and chickenpox side by side, and a number of clinical facts made differentiation possible. Chief among these facts was the low mortality of milkpox. There is nothing to oppose the view that alastrim has developed from smallpox through modification of the virus, but such an assumption does not invalidate the contention that alastrim is a distinct disease. The history of the three affections reveals the gradual substitution of alastrim for smallpox and chickenpox. This lends support to the belief in the development of a varioloid, due to a definite micro-organism less virulent than that of smallpox, yet more virulent than that of chickenpox and foreign to that of cowpox. 2. Vaccination against smallpox failed to protect in the epidemic of alastrim in Stanley Pool. Furthermore, persons who have recovered from alastrim frequently contract cowpox. 3. While the virus of alastrim resembles that of smallpox in its clinical manifestations, it shows little affinity for animals usually receptive to smallpox. It has never been transmitted to rabbits, calves or goats, and one has to resort to an artifice to transmit it to a monkey. Furthermore (*a*) cowpox does not immunize the monkey against inoculation with alastrim; (*b*) alastrim does not immunize the monkey against inoculation with smallpox vaccine, and (*c*) the virus of alastrim immediately affects the monkey so that inoculation by the cutaneous route provokes a generalized condition in most cases. It takes on thus an "allergic" form which it retains on inoculation into man by the cutaneous route. Van Hoof points out that as a therapeutic agent the allergic virus taken from the monkey induces in man earlier and less intense reactions and that these are not followed by generalization phenomena. A state of immunity should be created. If cultivated in receptive animals, it will furnish a specifically active lymph.

Bayer 205 in the Treatment of Trypanosomiasis in Animals

In the veterinary laboratory of Ruanda-Urundi, R. Van Saceghem has been studying the use of Bayer 205 in the treatment of trypanosomiasis in animals. He found the results disappointing after the observations on the use of the drug in treatment of small laboratory animals. Doses of 15 Gm. of Bayer 205 per hundred kilograms live weight are fatal for cattle. At necropsy, lesions of the liver, intestine and kidneys were found, while the blood was not coagulated. Bayer 205 rapidly establishes tolerance. Successive doses, as well as single doses, effect only transient sterilization. Bayer 205 is more active against *Trypanosoma congolense* than against *T. vivax*. A dose of 5 Gm. of Bayer 205 per hundred kilograms live weight will not protect an animal that is inoculated at the same time with 5 cc. of blood infected with *Trypanosoma congolense*.

Floods

The Meuse basin and a portion of the region watered by the Scheldt have suffered serious damage from floods. Numerous committees have been formed to relieve the distress. The king and queen have contributed 2,000,000 francs (about $69,000). The Red Cross of Belgium immediately set to work to provide aid for the sufferers. Numerous contributions, among others, a considerable sum from the American

Red Cross Society, have been received. In addition, the sanitary situation is menaced by the pollution of homes, and in some sections the water supply has been contaminated. All the public services and the health officers are doing their utmost. Physicians in all parts of the country are lending their aid.

GENEVA

(From Our Regular Correspondent)

March 12, 1926.

Influence of Hydrogen Ion Concentration on Anthrax Bacillus

Some important research on the influence of hydrogen ion concentration on the anthrax bacillus has recently been carried on by Dr. S. H. Whitworth at the Institute of Veterinary Pathology of the University of Zurich. The heat resistance of anthrax spores depends not only on the temperature but also on the hydrogen ion concentration of the medium in which they are suspended. Therefore all declarations as to the heat resistance of anthrax spores in liquid mediums or probably in live steam must give not only the time within which the spores die at a certain temperature but also the p_H of the medium. If spores are taken from any solution without being washed, and are then dried, their surfaces will hold a certain amount of substances carried from the medium. If these spores are put in flowing steam, these substances will be diluted again, so that the spore is really surrounded by a film of solution with a certain composition and with a certain concentration of hydrogen ions. Therefore the definition of heat resistance of anthrax spores should give indications of the composition of the medium in which the spores are suspended during heating, or where they have been suspended before drying. It would seem advisable when practicable, in the disinfection of material infected by anthrax spores, to acidify the medium. That viability depends greatly on the p_H of the medium has been shown by other investigators working with other pathogenic organisms. A few species of pathogenic bacteria die after a certain time in the soil. The time in which they die will vary according to the species, the nature of the soil, and the p_H value of the soil. In soil containing a certain proportion of organic material, the hydrogen ion concentration may be changed by bacterial growth to such an extent that the organisms die. On the other hand, the change may be favorable to the existence of spores.

These researches may be thus summarized: The heat resistance of anthrax spores is influenced by the hydrogen ion concentration and the composition of the medium in which they are suspended. The optimal p_H for resistance is in the region of 7.0 (at 85 C.). There is a decrease in the resistance at any temperature, with a decrease in p_H below 7.0. This decrease in the resistance is considerable at p_H 6.5, is very marked at p_H 6.0, and is still more marked with further decrease of p_H. The resistance is decreased with increase in alkalinity, but this decrease in resistance is not so marked as on the acid side. Anthrax spores suspended in fifteenth molar phosphate mixtures show greater resistance to heat at 85 C. than those suspended in broth or in broth + 3 per cent gelatin, and the resistance is greater in the latter than in ordinary broth. There is a great variation in the heat resistance of individual spores. Some spores will survive heating for considerable periods in a medium of very low p_H.

Revision of International Sanitary Convention

At the recent meeting of the permanent committee of the International Bureau of Public Hygiene, a number of questions relating to the revision of the international sanitary convention of 1912 were examined. Detailed attention was given to special provisions which may eventually be proposed concerning the Far Eastern countries. The committee received the report of the fifth session of the committee of hygiene of the League of Nations, held in Geneva in October, 1925, whose resolutions were approved by the international bureau. One of the resolutions of the Committee of Hygiene of the League of Nations was concerned with the forthcoming decennial revision of the international list of diseases and of causes of death. At the last meeting of the international commission (held in 1920), which was charged with the decennial revision, the nomenclature could not be communicated to the interested governments in definite form until 1924. At present only Great Britain and the United States have adopted this nomenclature, and the committee voiced the hope that other nations would adopt it soon. The committee accepted its responsibilities under articles 8 and 10 of the international opium convention, signed at Geneva, Feb. 19, 1925. Communications to the committee concerning cholera in British India show that the Bengal delta is the endemic focus of this disease. The Indian government has undertaken to use all possible measures against cholera. Active propaganda can extend anticholera vaccination among the Asiatic natives without making it compulsory, as is proved by the results obtained in Dutch India. Vaccination of pilgrims against cholera is to be proposed in Egypt. New data were received from British India, Manchuria, Netherlands and the United States on rodents and their cutaneous parasites, and will be published later in the general report.

A plan was considered for research work leading to revision of the pathology and prophylaxis of human variola. This will be carried out through investigations made by members of the committee of the international bureau of public hygiene and the Committee of Hygiene of the League of Nations, competent specialists of different countries and researches in various selected laboratories. Various other communications were received concerning variola and alastrim in Belgium, England and British India.

Papers were presented dealing with the frequency of locomotor ataxia and general paralysis in British India and Bulgaria, and on the results of investigations made in England on the occurrence of these diseases in soldier beneficiaries of war pensions. This investigation was concerned with about 100,000 subjects treated during the war with arsphenamine, who could be closely followed. Of these only ten developed tabes or paralysis. This result favors the thesis that arsenical treatment tends to decrease rather than to increase the proportion of tabetic and paralytic patients. Still, further investigations are necessary, and the committee has decided to examine the influence of race, mode of life and other circumstances on the frequency of tabes and general paralysis in different countries. The malaria treatment of general paralysis will receive further investigation.

A preliminary report on scarlet fever based on investigations made by the committee was discussed. Other papers concerned scarlet fever in Bulgaria, Czechoslovakia, Greece, Japan, Poland, South Africa and Switzerland. Vaccination with Gabritchevsky's vaccine, immunologic experiments, immunization with Dick's toxin and treatment with convalescent serum are all open to investigators. The general opinion was that terminal disinfection has no prophylactic value in scarlet fever and other contagious diseases.

Another discussion revealed the fact that legislation in various countries concerning biologic products and arsphenamine is divergent in its principles and application. Some countries control manufacture of the preparations; others merely control their sale. Various other communications were presented concerning diseases of the Mediterranean basin; infantile kala-azar and other leishmaniases; dissemination of leprosy; epidemic icterus; the part played by railroads in the spread of infectious diseases; scurvy, and the results of combating syphilis in Algeria.

JAPAN

(From Our Regular Correspondent)

Kyoto, March 8, 1926.

New Universities

The opening ceremony of the Korea Imperial University is to be held, April 1. About three weeks before that the following appointments will be made: Prof. Unokichi Hattori, Litt.D., as president, and various professors as deans of faculty in the institution. Appointment of the other professors will be made public after the ceremony at the beginning of April. It is settled that Prof. Dr. Kiyoshi Shiga will be a senior professor of the medical college.

According to the announcement made by the department of education, another imperial university, including a medical college, will be established in Formosa in April, 1928. It is reported that some professors and instructors will be sent abroad to study medical science.

Military Ambulance Airplanes

According to the health department of the League of Nations, the Japanese army has decided to organize an aerial ambulance corps. The newly built planes can carry five men at a time—two patients, an army surgeon, a hospital sergeant major and the pilot. The trial flight made at the Tokorozawa aerodrome some days ago proved that the machine has unique merits.

Fecundity of Young Married Japanese Women

Statistics made public by Dr. Ryuichi Susaki following his investigation of 414 married Japanese women show that the greatest number marry at the age of 19. Next in order are those of 20 and 18 years. Irrespective of the age when married, the majority become pregnant in the third month of married life. In 84.9 per cent of cases the first children were born in the first three years after marriage. Of the 414 women, those who first menstruated at 14 or 15 years of age were most likely to conceive early in married life. Many of those who first menstruated at 14 years of age and married at 22 conceived in the first month of married life. Marriage between acquaintances or relatives gives the highest rate of early conception; that of illicit union, the lowest. Generally speaking, those who conceived for the first time during the first three years of married life were those whose husbands were not more than eight years older than themselves. The interval between the first birth and the second was in most cases from 1.1 to 2.5 years.

Japanese Practitioners in the Far East

The number of Japanese practitioners in China and other parts of the Far East is increasing each year. According to the latest investigation made by the department of foreign affairs of Japan, not less than 600 are in practice in South China, including Shanghai and Hongkong, where their number is respectively larger than in any other place. It is sure that they are practicing medicine in those parts of the world, though it is uncertain whether all of them are registered in the practitioners' list of the Japanese government. In Singapore, Dutch India, and many neighboring provinces and countries, nearly the same number of Japanese practitioners as in South China have also been establishing themselves in practice.

The Keio Dietetic Laboratory

A dietetic laboratory in the Medical College of Keio University will be ready for use by next July. The structure of the laboratory is nearly the same as the rooms for bedside and clinical training in the same institution, except that there is added a culinary room perfectly furnished for research. The faculty will consist of a professor, an assistant professor, two instructors and several assistants. The main object is clinical research in vegetable dietetics under the direction of the professor. Prof. Dr. Kenta Mori is to be head of the faculty, and Mr. Minoru Hara, B.A.S., of the government dietetic laboratory, the assistant professor.

Achard in Japan

Dr. Charles Achard, professor in the University of Paris and general secretary of the medical section of the French Academy, arrived in this country, March 18, for a three months' investigation of medical facilities in Japan. He is scheduled to lecture in each medical college while in Tokyo. The Japan Medical Association, which is to hold its general meeting in April, will ask him to be present as an invited guest.

An Improved Crematory

Dr. Shige Koike of the Sasaki Kyoundo Hospital, Tokyo, has constructed an improved crematory. Recently he made an announcement about his apparatus, which possesses the following merits: It is utterly smokeless and odorless. Since it takes only an hour or so to cremate a body, it is economical of time and money. The bereaved may take back the ashes with them on the day they come. Thus the dignity of the dead is not violated. Since little fuel is needed, the cost of cremating a body is but half a dollar or so. Since neither a chimney nor a big site is necessary, construction is inexpensive. It may be built even in crowded parts of towns. Since it is simple to operate, no expert is needed.

ITALY

(From Our Regular Correspondent)

Feb. 15, 1926.

The Course in Hygiene Organized by the Red Cross Society

The Italian Red Cross Society plans to organize, February 1, its fourth course in hygiene and medical child welfare work in the Emilio Maraini antituberculosis preventorium in Rome. The object of the course is to demonstrate to physicians the modern technic of child hygiene and child welfare. The course will be conducted by Professor Valagussa, director of the preventorium, and will extend over four months, at the end of which time those who have attended will be given a diploma, and, in addition, prizes will be bestowed on those who did especially good work. The Red Cross will regard the diploma as entitling the holder to special consideration in the selection of personnel to aid in carrying out the educational campaign that it expects to launch later.

Donations to Scientific Institutes

In memory of Dr. Ognibene, his widow has recently given the University of Modena 80,000 liras, with which to establish two Ognibene prizes open to students of the college of medicine. To the same university, there has recently been presented about 1,000,000 liras, the gift of Dr. Araoz, director general of the public health service in Argentina and professor at the Faculty of Medicine in Buenos Aires. The money is to be used to found a university institute to promote tuberculosis prophylaxis.

The Twenty-Fourth Congress of Obstetrics and Gynecology

The twenty-fourth session of the Società italiana di ostetricia e ginecologia was held in Rome, December 17-19, under the chairmanship of Senator Pestalozza, professor in the University of Rome. After referring to recent advances in obstetrics, Professor Pestalozza briefly reviewed the history of the Roman school, which, founded by Asdrubali in 1787, numbered among its members some eminent teachers and made noteworthy contributions in its field.

The scientific work of the congress was begun with the paper by Professor Decio, director of the obstetric clinic at the University of Siena, who treated the theme: The Constitutional Type in Relation to Gynecologic Diseases. The essayist recalled the varied criteria on which we must base our determination of the constitutional type. The influence of the type is manifested not only in sexual development but also in the evolution of gynecologic diseases. The writer emphasized that a better knowledge of constitutional factors would result in more rational treatment, and that treatment would consist in procedures intended to improve the constitution of the subject: climatotherapy, physical exercise, hydrotherapy, organotherapy, venesection.

Dr. Temesvary discussed constitutional abnormalities as an etiologic factor in hernias of women. Dr. Orru spoke on a virilism as a result of ovarian tumor, and Professor Bompiani took up venesection in the treatment of some cases of altered menstrual function. A long discussion followed, which was closed by Professor Decio.

The second main theme on the program was "Diseases of the Endocrine System in Relation to Pregnancy," on which a paper was presented by Professor Gentili, director of the Clinica ostetrica-ginecologica at the University of Pisa. Following the papèr there was a general discussion. Professor Gentili replied to all who discussed the question.

A resolution was passed to devote the next congress to a celebration in honor of the founders of the society who are still living; namely, Professors Bedeschi, Fabbri, Guzzoni degli Ancarani, Mangiagalli, Negri and Pestalozza.

Convention of the Italian Society of Dermatology and Syphilography

The Società italiana di dermatologia e sifilografia held its twenty-second annual session in Rome, December 17-19. Prof. Jader Cappelli, director of the Clinica dermosifilopatica at the University of Turin, presided. The main subject on the program, "The Pathogenesis of Congenital Syphilis," was presented by Prôfessor Lombardo of Pisa. Communications on subjects related to the main theme were presented by Martinotti, Piccardi and Artom. The lively general discussion which followed was closed by Professor Lombardo. Professor Bosellini, director of the Clinica dermosifilopatica at Rome, was chosen president for the ensuing year.

Activities of the Italian League to Combat Cancer

The governing council of the Lega italiana per la lotta contro il cancro has recently published a report for 1925. The league has two aims: (1) to promote more exact knowledge and more effective treatment of cancer, and (2) to support propaganda for early diagnosis of the disease and for the prophylactic treatment of the lesions that predispose toward it. The league was founded in Bologna in 1922. In September, 1924, at Milan, the league was reorganized on a broader basis. Acting with a national committee appointed by the Red Cross, the league is planning to found in Milan an institute for cancer research, which will be the first institute of the kind to be established in Italy. During the past year, the league has developed through the organization of diagnostic centers and through regional committees established in the provinces. Of the latter, twenty-eight have already been established in Italy, in addition to one in Alexandria, Egypt. Thirty-one others are being organized, and it is expected that, very shortly, such committees will be functioning in all the provinces of the realm, as well as in many Italian colonies in foreign lands.

The work of organization was accompanied by a publicity campaign carried on by means of lectures and the distribution of pamphlets and leaflets. Lectures were held in Florence, Siena and Palermo. Among the pamphlets distributed was one by Professor Vernoni of the University of Florence, entitled "Cancer and the Means of Combating It" and another by Professor Rietti of Ferrara on the subject of "Anticancer Organizations, with Especial Reference to the Institutes Existing in Foreign Countries for the Study and Treatment of Cancer." There is also a publication in course of preparation by Professor Alessandrini, instructor in parasitology at the University of Rome.

The minister of the interior has given his support to the publicity campaign, has appropriated funds to aid in carrying on the work, and has requested the prefects of the provinces to stimulate local initiative and the organization of committees to provide for the coordination of existing movements. In addition, the public health service has sent a questionnaire to the physicians in the province, in which it requests data concerning local societies for combating cancer, special dispensaries or ambulatoriums, diagnostic centers, clinics or hospital wards for the treatment of cancer patients, and roentgenologic or radium therapy establishments. The president of the league has also appealed to the ministers having jurisdiction to see to it that the distribution of radium among the hospitals and clinics, for therapeutic purposes, be better controlled. Many banking houses, provincial deputations, communes and societies for the promotion of public welfare have contributed to the league.

A Graduate Course in Industrial Medicine

In the clinic for occupational diseases at the University of Naples, a graduate course in industrial medicine, extending from January 25 to March 25, has been announced. The course, intended solely for physicians, will consist of lectures, clinical and laboratory work, and visits to industrial establishments and to institutes of social welfare.

BERLIN

(From Our Regular Correspondent)

Feb. 27, 1926.

Relative Sexuality

Before the Berliner medizinische Gesellschaft, Prof. M. Hartmann, whose researches on protozoa are well known, delivered an address recently on relative sexuality and its importance to fecundation. From numerous observations, partly his own and partly those of others, Hartmann concludes that every living cell is bisexual and possesses the complete female and male anlagen. That eventually the female or the male potentiality becomes preponderant is owing to the fact that one anlage is furthered or exists in a naturally dominant form, whereas the other anlage is either retarded or is less dominant. As the result of the preponderant influence of one or the other factor, a cell becomes definitely male or female with reference to another cell in which the opposite factor predominates. The female and male germinal cells are therefore not purely and absolutely female or male but are only relatively so. Hartmann assumes that the difference in sex is based on quantitative and not qualitative differences. Fortified by this conception, Hartmann had formerly reached the conclusion that in lower organisms there may be not merely two extremes of sexual differentiation but possibly several degrees marking distinctions of sex. Recently Hartmann has found evidence in support of such an assumption. At the German Zoological Station in Naples, he investigated the sexual behavior of a specimen of algae of the genus *Ectocarpus*. This species belongs to one of those lowest forms of organisms whose germinal cells cannot, from their external appearance, be classified as male and female. Each individual of the species produces minute germinal cells provided with an anterior and a posterior flagellum and resembling *Flagellata* in other respects as well, which *inter se* are morphologically alike (isogametes). But that these isogametes are, in fact, physiologically differentiated is shown, with respect to *Ectocarpus*, by the observation that only gametes that are produced by different plants are brought into sexual union, and the behavior of the various gametes is such that some may be regarded as male and some as female. When union of the gametes has occurred, certain ones, thus marked as female, lose their motility and attach themselves to the bottom of the container, while the others comport themselves as male germinal cells, for they hover about the female cells in large numbers until finally a union of a male germinal cell with the sedentary or sessile female cell takes place. Hartmann observed that it was possible to distinguish strong, less strong and weak females, the same being true of the males. When Hartmann brought together types that had been recognized as weakly masculine with types that he had found to be strongly masculine, these "isosexual" gametes effected a sexual union, the weakly male gametes comporting themselves now as female. The corresponding observation was made that weakly female gametes entered into sexual union with strongly female gametes, the weakly female gametes functioning now as male gametes. It is evident, therefore, that individual gametes are not absolutely male or female. Whether a sexual union takes place between two gametes does not depend on qualitative but rather on quantitative differences. How these differences in constitutional makeup are brought about remains to be determined, but Hartmann is inclined to the view that external conditions are the deciding factors.

Statistics of Medical Students at Prussian Universities

The Prussian Bureau of Statistics published recently statistical data on the students at Prussian universities. The total number of medical students, nationals and foreigners included, during the winter semester, was 3,387 men and 659 women. There were three men and two women under 18 years of age, and 178 men and twenty-six women over 30 years old. The remainder ranged in age between 18 and 30. The distribution of students according to confession was as shown in the adjoining table.

Confession	Men	Women
Protestant	1,734	319
Roman Catholic	809	136
Jewish	412	118
No religious confession	30	13
Miscellaneous (Mohammedan, etc.)	257	38

There were more students in their tenth semester than any other: 576 men and 100 women. (The medical course in Germany covers ten semesters.) In their eleventh semester there were 130 men and twelve women; 116 men and eight women were in their twelfth semester or above.

Of the medical students, 2,354 men and 419 women were planning to become physicians, while 327 men and 79 women were intending to practice dentistry.

There were 1,988 students with diplomas from humanistic (classical) gymnasia and 985 students from the "Realgymnasia" (no instruction in Greek).

A record of the profession or occupation of the fathers of the students yielded the following result: high officials, 353 men students and 114 women; officials of the middle type, 635 men and 102 women; government clerks, 35 men and 1 woman; the liberal professions (physicians, etc.), 579 men and 89 women; independent callings without academic training, 76 men and 10 women; army or navy officers and higher officials, 45 men and 10 women; other military persons, 2 men and 3 women; landed proprietors, 76 men and 16 women; farmers and small landowners, 200 men and 16 women; industrialists, 886 men and 194 women (among these, 113 and 47, respectively, were owners or managers of factories): craftsmen, 154 men and 19 women; employees in leading positions, 104 men and 15 women; employees in minor positions, 201 men and 47 women; laborers, 17 men and 1 woman; no occupation, 52 men and 17 women.

Marriages

Cecil B. O'Brien, Greencastle, Ind., to Miss Edna Louise Koss of Indianapolis, January 20.

John O. Cletcher, Tuscola, Ill., to Miss Jessie Wilson of Flushing, Ohio, in February.

Otis W. McQuown, Marion, Ind., to Miss Harriet Joost of Chicago, Dec. 31, 1925.

Deaths

Jesse Ralph Harris ⊕ Lieut. Col., U. S. Army, retired, Niagara Falls, N. Y.; University of Buffalo, Department of Medicine, 1901; assistant in anatomy Cornell University *Medical College, 1901-1902*; was commissioned in the U. S. Army in 1902 and retired as lieutenant colonel in 1919 on account of physical disability; since retiring was health officer of New Britain, Conn., and Tampa, Fla.; connected with the Tennessee State Board of Health, 1923-1924; aged 51; died, February 6, of cerebral hemorrhage.

Jacob Edward Gilcreest ⊕ Ennis, Texas; Louisville (Ky.) Medical College, 1876; past president of the Texas State Medical Association and the Cook County Medical Society; emeritus professor of gynecology and formerly lecturer on gynecology, Baylor University College of Medicine, Dallas; member of the state board of health, 1909-1911; at one time chief surgeon of the Gainesville (Texas) Sanitarium; aged 75; died, March 18, of myocarditis.

Cyrus Strong Merrill, Albany, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1871; member of the Medical Society of the State of New York, and the American Ophthalmological Society; emeritus professor of ophthalmology and otology, Albany Medical College, since 1876; on the staffs of the Albany and Child's hospitals; aged 78; died, March 17.

Mack Rogers ⊕ Birmingham, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1889; formerly professor of anatomy, Birmingham Medical College; was a member of the House of Delegates of the American Medical Association, 1909 and 1910; at one time vice president of the Southern Medical Association; served during the World War; connected with the U. S. Veterans' Hospital, no. 99, Excelsior Springs, Mo.; aged 61; died, March 20, of heart disease.

Walter Scott Dotson ⊕ Lebanon, Tenn.; University of Nashville Medical Department, 1901; formerly secretary of the Wilson County Medical Society; served during the World War; on the staff of McFarland Hospital; aged 47; died, March 13, at the Protestant Hospital, Nashville, of cerebral hemorrhage.

Hartwig Kandt ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1906; member of the American College of Physicians and Brooklyn Society of Internal Medicine; on the staffs of the Methodist Episcopal, and the Wyckoff Heights hospitals; aged 50; died, March 25, of pneumonia.

Nelson Water Thompson, Port Chester, N. Y.; University of Michigan Homeopathic Medical School, Ann Arbor, 1901; formerly on the staff of the Metropolitan Hospital, New York; medical superintendent of the United Hospital, where he died, March 18, of heart disease, aged 49.

Thomas Joseph Kilmartin, Waterbury, Conn.; Medical Department of the University of the City of New York, 1895; member of the Connecticut State Medical Society; for nineteen years city health officer; aged 53; died, March 13, of chronic endocarditis and myocarditis.

Albert Polon, New York; Cornell University Medical College, Ithaca, 1910; member of the Medical Society of the State of New York; instructor in neurology, Columbia University College of Physicians and Surgeons, New York; aged 44; died, March 15, of heart disease.

Raymond Albert Rice ⊕ Columbus, Ohio; Starling Medical College, Columbus, 1897; member of the Associated Anesthetists of the United States and Canada; on the staff of the Grant Hospital; aged 50; died suddenly, March 11, at New Orleans, of heart disease.

Philip Turner Southall, Amelia, C. H., Va.; Medical College of Virginia, Richmond, 1873; member of the Medical Society of Virginia; president of the Amelia County Medical

Society; at one time member of the county board of health; aged 74; died, February 16.

Charles Pinckney Hough ⊕ Jefferson City, Mo.; Missouri Medical College, St. Louis, 1875; formerly surgeon general of the Montana National Guard; at one time health officer of Butte, Mont., and on the staff of the St. James' Hospital; aged 80; died, March 12.

Stephen White Roof ⊕ University and Bellevue Hospital Medical College, New York, 1906; on the staffs of the Nyack (N. Y.) Hospital and the Manhattan Eye, Ear and Throat Hospital; served during the World War; aged 50; died, March 13.

Abbott B. Lichtenwalner, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1891; member of the Medical Society of the State of Pennsylvania; aged 64; died in March, at the Hahnemann Hospital, of chronic myocarditis.

Henry Moffat ⊕ Yonkers, N. Y.; Medical Department of Columbia College, New York, 1881; on the staffs of the Ossining (N. Y.) Hospital, the Sprain Ridge and St. Joseph's hospitals, Yonkers; aged 70; died, March 25, of heart disease.

William Garth Clopton ⊕ Baltimore; University of the South Medical Department, Sewanee, Tenn., 1904; aged 48; died, March 16, at the Massachusetts General Hospital, Boston, following an operation for carcinoma of the rectum.

John A. Sheibley, Shermans Dale, Pa.; University of Pittsburgh School of Medicine, 1891; member of the Medical Society of the State of Pennsylvania; formerly member and president of the school board; aged 67; died, March 15.

Willis Beecher Moodie, Valhalla, N. Y.; University of Vermont College of Medicine, Burlington, 1909; member of the Medical Society of the State of New York; aged 42; died, March 5, of streptococcic septicemia and diabetes.

Frank Forrest Floyd ⊕ Statesboro, Ga.; University of Georgia Medical Department, Augusta, 1899; secretary of the Bullock County Medical Society; served during the World War; aged 50; died, March 11, of pneumonia.

John T. Wallingford, Covington, Ky.; Medical College of Ohio, Cincinnati, 1882; formerly health officer of Covington; aged 68; died in March, at Brentwood Heights, Calif., of acute myocarditis and hypostatic pneumonia.

William Henry Katzenbach ⊕ New York; Bellevue Hospital Medical College, New York, 1871; formerly professor of clinical medicine, New York Polyclinic Medical School; aged 78; died, March 19, at Trenton, N. J.

Samuel Wood Thurber ⊕ New York; Medical Department of Columbia College, New York, 1894; formerly instructor of laryngology, Columbia University College of Physicians and Surgeons; aged 58; died, March 16.

John W. Cline ⊕ Santa Rosa, Calif.; College of Physicians and Surgeons, Keokuk, 1881; Bellevue Hospital Medical College, New York, 1894; aged 65; died, Dec. 24, 1925, of chronic myocarditis and chronic nephritis.

Roscoe Lee Logan ⊕ San Rafael, Calif.; California Eclectic Medical College, Los Angeles, 1901; aged 50; died, March 7, at St. Francis Hospital, San Francisco, of lobar pneumonia, and acute hepatitis.

Harry Schuyler Oyler ⊕ Lincoln, Ill.; Marion-Sims College of Medicine, St. Louis, 1901; served during the World War; aged 55; died in March, at the Deaconess Hospital, of interstitial nephritis.

William Walter Barrett, Peachland, N. C.; Kentucky School of Medicine, Louisville, 1892; aged 61; died, March 11, at the Anson Sanatorium, Wadesboro, of injuries received in a fall.

William Kline ⊕ Phillipsburg, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1891; on the staff of the Warren Hospital, where he died, March 3, of heart disease, aged 60.

Shelby Harrison Kelsay, Cropper, Ky.; Kentucky University Medical Department, Louisville, 1904; member of the Kentucky State Medical Association; aged 46; died, March 14, of pneumonia.

James Wesley Cartwright ⊕ Payne, Ohio; Long Island College Hospital, Brooklyn, 1882; Fort Wayne (Ind.) College of Medicine, 1892; aged 69; died, March 15, at Jacksonville, Fla.

Isaac L. Coy, Archbold, Ohio; Cincinnati College of Medicine and Surgery, 1898; member of the Ohio State Medical Association; aged 66; died suddenly, March 17, of cerebral hemorrhage.

Albert Joseph Kopf ⊕ Denver; Marion-Sims College of Medicine, St. Louis, 1899; member of the Missouri State Medical Association; aged 57; died, March 1, at St. Luke's Hospital.

Louis Brechemin ⊕ Col., U. S. Army, retired, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1876; served during the World War; aged 73; died, March 11.

Jared Charles Hepburn ⊕ Chicago; Chicago Medical College, 1890; on the staff of St. Bernard's Hospital; aged 62; died, March 17, at Phoenix, Ariz., of heart disease.

Harold Jerard ⊕ Pleasant Hill, Mo.; University of Missouri School of Medicine, Columbia, 1875; aged 73; died, March 14, at the Research Hospital, Kansas City.

Rex Alexander Schlag, Prairie du Sac, Wis.; Denver and Gross College of Medicine, Medical Department University of Denver, 1903; aged 46; died, March 9.

Julius Garst, Worcester, Mass.; University of Michigan Medical School, Ann Arbor, 1878; also a pharmacist; aged 70; died recently, at Roswell, N. M.

Aden G. Lovell ⊕ Mount Vernon, Ky.; Louisville Medical College, 1883; president of the Rockcastle County Medical Society; aged 72; died, March 11.

Alfred Carson Williams ⊕ Reynolds, Ind.; Indiana University School of Medicine, Indianapolis, 1912; aged 36; died, March 17, of bronchopneumonia.

Hudson Jerome Kinne, Frankfort, Mich.; Baltimore Medical College, 1892; aged 64; died, March 18, at a sanatorium in Battle Creek, of myocarditis.

Edward J. Gabriel ⊕ Payson, Ill.; St. Louis College of Physicians and Surgeons, 1891; aged 57; died, March 11, at the Blessing Hospital, Quincy.

William Henry Holland, Ninety Six, S. C.; University of Maryland School of Medicine, Baltimore, 1891; also a dentist; aged 62; died, March 7.

Newton M. Williams, Jackson, Tenn.; University of Louisville (Ky.) School of Medicine, 1890; aged 77; died, March 11, of chronic nephritis.

John B. Campbell, Brooklyn; New York Homeopathic Medical College, New York, 1878; aged 60; died, March 2, of cerebral hemorrhage.

Benjamin Robley Lennox, Sikeston, Mo.; Missouri Medical College, St. Louis, 1884; aged 67; died, March 6, following a long illness.

Henry Bell King ⊕ York, Pa.; Jefferson Medical College of Philadelphia, 1883; aged 65; died, January 24, of chronic myocarditis.

Daniel Alcott Holland ⊕ Winfield, Kan.; University of Louisville School of Medicine, 1909; aged 42; died, March 7, of influenza.

Charles Henry Walker, New York; Medical Department of the University of the City of New York, 1894; aged 59; died, March 16.

William R. Siron, McDowell, Va.; University of Maryland School of Medicine, Baltimore, 1891; aged 61; died, February 16.

Samuel Lee Stonebraker ⊕ Tyrone, Pa.; College of Physicians and Surgeons, Baltimore, 1905; aged 45; died, February 25.

Harry Keep Lum ⊕ Monroe, Wash.; University of Michigan Medical School, Ann Arbor, 1885; aged 63; died, February 15.

Peter J. Lenhart, Wauseon, Ohio; University of Wooster Medical Department, Cleveland, 1875; aged 78; died in March.

Kelley W. Travis, Princeton, Mo.; American Medical College, St. Louis, 1879; aged 73; died, March 7, of pneumonia.

Clinton G. Buffington, Decatur, Ill.; Missouri Medical College, St. Louis, 1881; aged 66; died suddenly, March 14.

Lucius G. Waterman ⊕ Buffalo; University of Buffalo Department of Medicine, 1883; aged 77; died, March 11.

Clayton A. Bullard, Royal Oak, Mich.; Detroit College of Medicine and Surgery, 1902; aged 48; died, March 2.

Wallace Mathews ⊕ Quitman, Ga.; Atlanta Medical College, 1890; aged 58; was found dead, March 11.

Clifford R. Case, Cincinnati; Medical College of Ohio, Cincinnati, 1888; aged 64; died, March 12.

Thomas N. Courson, Devereux, Ga.; Southern Medical College, Atlanta, 1886; died, March 9.

Thomas Henry Lindley, Cedar Rapids, Iowa (licensed, Iowa, 1889); aged 81; died, March 8.

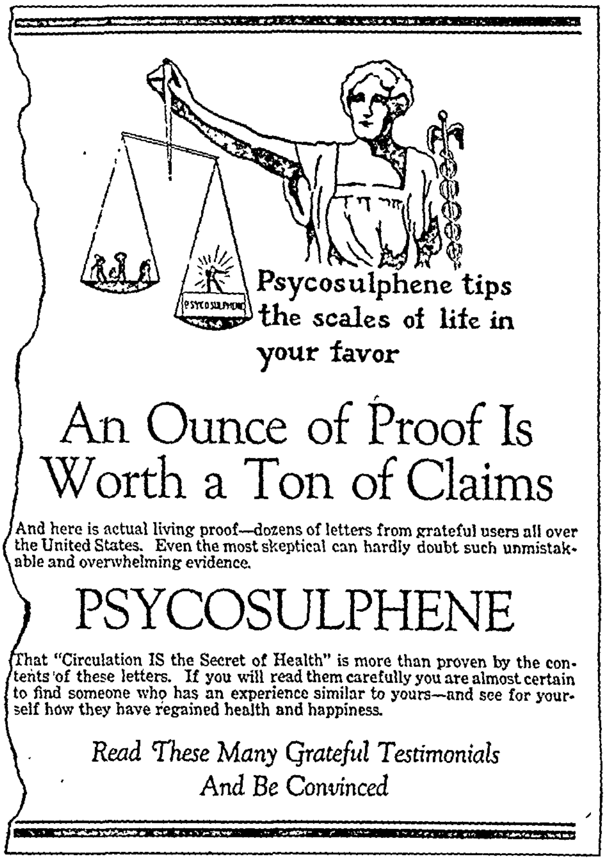
PSYCOSULPHENE

Spring Hill, W. Va., Seeks a Place in the Sun of Quackery

From that metropolitan center (population 200), Spring Hill, West Virginia, comes the latest medical marvel, "Psycosulphene," exclusively distributed by McNickle & Co. Psycosulphene is "a Product of Chemical Research"—take it from the manufacturer. It "Promotes Circulation Through the Feet." Those who are suffering from "kidney trouble," "run down constitution," "nervous disorders" or what-have-you, are instructed to drop a small pinch of Psycosulphene into each shoe each day. "The thoughtless will smile, but the wise know there are 27,000,000 pores in the soles of your feet."



Psycosulphene tips the scales of life in your favor

An Ounce of Proof Is Worth a Ton of Claims

And here is actual living proof—dozens of letters from grateful users all over the United States. Even the most skeptical can hardly doubt such unmistakable and overwhelming evidence.

PSYCOSULPHENE

That "Circulation IS the Secret of Health" is more than proven by the contents of these letters. If you will read them carefully you are almost certain to find someone who has an experience similar to yours—and see for yourself how they have regained health and happiness.

Read These Many Grateful Testimonials And Be Convinced

This brand of quackery appears to be profitable: for instance, in the Charleston (W. Va.) *Gazette* for Jan. 19, 1926, appear four full-page advertisements of "Psycosulphene! The Wonder Treatment." No small proportion of the white paper thus used up is devoted to the ubiquitous and inevitable testimonial. We learn that Mrs. P. R. O'Dell of Charleston was a cripple with rheumatism; she was either confined in bed or walking around on crutches; her heart was affected, too, and her eyes were poor, and she was so weak that she could not "wring a dish-rag." Then Psycosulphene came into her life and in just three weeks by putting a pinch of this marvelous powder into the foot of each stocking, she became entirely well. Moreover, she lost "twenty pounds of unnatural weight."

Mrs. W. H. Fish of Columbus, Ohio, is another testimonial giver, not on behalf of herself, but in the interest of her husband. Mr. Fish, it seems, suffered from rheumatism; worse still, "he was attended by twenty-nine different doctors." Then came Psycosulphene, and Mr. Fish "began to sleep and enjoy life again." May Albertson had long suffered from malnutrition. After she "had doctored for seven years" she heard of Psycosulphene and her color came back. She gained eleven pounds in four weeks.

Mrs. Ralph Fox of Pennsylvania "suffered from a nervous breakdown" and after spending $200 in doctors' bills without effect and being confined to her bed for seven years, she put Psycosulphene into her stockings. Now she can take care of her housework! Another Charleston citizen, Mr. P. C. Bays, had eczema for fifteen years. He began using Psycosulphene and he "scaled off like a fish" and is completely cured. Then there was Peter Adams, who was cured of asthma, and Mrs. Nellie Allard, who recovered via the Psycosulphene route from swollen feet and hysterics.

These are just a few of the wonders that the Charleston *Gazette* passes on (At the usual advertising rates?) to others who may be suffering from rheumatism, nervous breakdown, malnutrition, swollen feet or hysterics. Not that the conditions just enumerated exhaust the field covered by Psycosulphene. This powder, a pinch of which is to be put in one's socks, is the "last word" in such conditions as "blood poisoning," anemia, "female trouble" or "prostate gland trouble."

In this same advertisement we are told that while "clap-trap and ballyhoo were never more in vogue than today," yet "the great forces of Nature are silent," which presumably explains why the Psycosulphene advertisement shouts raucously from four full pages of the Charleston *Gazette* in letters that can be read a block away.

As already mentioned, Psycosulphene is used externally. The instructions are to put five pinches of the powder in the stockings or socks the first day, four pinches the second day, three pinches the third day, two pinches the fourth day, and then one pinch for every day of the remaining seventy-two days that the preparation is to be used. For "best results" the purchaser is urged to wear the same stockings "from four to ten days"!

In order that the public and the medical profession might be apprised of the composition of this "product of chemical research" an original package of Psycosulphene was turned over to the A. M. A. Chemical Laboratory with the request that it be analyzed. The Laboratory Report follows:

LABORATORY REPORT

"One original package of Psycosulphene (McNickle & Co., Spring Hill, W. Va.) was submitted to the A. M. A. Chemical Laboratory for examination. The package contained 169 Gm. (approximately 6 ounces) of a pale yellowish white pulverized powder. No statement of the composition appeared on the package. Qualitative tests indicated the presence of sulphur, starch, boron and carbonates. Boron was present as sodium tetraborate (borax); the carbonate was present mainly as sodium bicarbonate. Alkaloids, heavy metals, benzoic and salicylic acids, camphor, essential oils were not found.

"Quantitative determinations yielded the following:

"Loss over sulphuric acid	2.7 per cent
"Sulphur	4.6 per cent
"Starch	16.6 per cent
"Bicarbonate and carbonate (as carbon dioxide — CO_2)	21.8 per cent
"Boric anhydride (B_2O_3)*	15.0 per cent

* The figures for B_2O_3 and CO_2 yield somewhat higher theoretical value for sodium borate ($Na_2B_4O_7.10\ H_2O$) and sodium bicarbonate ($NaHCO_3$), respectively, than are actually present; this is to be expected as the composition of both borax and sodium bicarbonate varies.

"From the foregoing it may be concluded that Psycosulphene contains essentially the following substances in the approximate amounts:

"Sulphur	5 parts
"Starch	15 parts
"Borax	40 parts
"Baking soda	40 parts"

Here, then, we have a few cents' worth of baking soda, borax, starch and sulphur mixed together, put in a fancy box, given a misleading name, and sold for $3.50. No wonder McNickle & Co. can afford to purchase four-page spreads in city newspapers. Supposing, however, our federal law required the declaration on the label of the names and quantities of the active ingredients of "patent medicines." How many people could be fooled into believing that a mixture of this sort will cure prostate trouble, blood poisoning, varicose veins, neuritis or the score of other conditions for which Psycosulphene is directly or by implication recommended? The medical faker will flourish just so long as secrecy and the mystery that goes with secrecy is permitted by law.

Correspondence

"POLLEN THERAPY WITH PROTEIN-FREE EXTRACTS"

To the Editor:—The article by Black and Moore (THE JOURNAL, January 30) contains statements that are distinctly inaccurate and misleading.

F. W. Heyl (*J. Am. Chem. Soc.* **39**:1470, 1917) found that ragweed pollen used in his work contained 4.99 per cent of total nitrogen, of which 2.6 per cent was soluble in aqueous saline solution. Of this 2.6 per cent, from 0.6 to 0.8 per cent was protein in nature, part being albumin and proteose.

H. L. Huber and K. K. Koessler (*Arch. Int. Med.* **36**:751 [Dec.] 1925) obtained solutions of ragweed pollen (1:10, or 10 per cent) which contained 1.54 and 1.61 mg. of nitrogen per cubic centimeter. According to Heyl's figures, these 10 per cent solutions would contain about 0.5 mg. of protein nitrogen per cubic centimeter, or about 3 mg. of pollen protein per cubic centimeter.

Glycerol and water have similar solvent properties. With regard to the nitrogenous constituents of *Artemisia* pollens, we have confirmed this general fact in that we find that glycerol-water-salt extracts and water-salt extracts of the same pollen concentrations contain identical amounts of nitrogen.

Various conditions may modify the usual qualitative protein tests, so that the failure to secure positive tests as Black did is not definite proof of the absence of protein. Further, it usually is considered most probable that protein is present in unpurified biologic extracts containing nitrogen (especially large amounts).

With especial regard to the testing of glycerol solutions of *Ambrosia trifida* pollen, we find the following:

A 2 per cent solution of pollen in 50 per cent glycerol-physiologic sodium chloride solution was used. It contains about 0.3 mg. of nitrogen per cubic centimeter.

In the biuret test, the color of the solution interferes with the recognition of the test. Reducing substances are present which render testing impossible, owing to the rapid reduction of the cupric ion in the alkaline solution.

The Adamkiewicz reaction is negative, but it is also negative with an egg-white solution in 50 per cent glycerol that contained 0.32 mg. of nitrogen per cubic centimeter.

In the Liebermann reaction, a slight red coloration occurs. This test is not definite.

In the xanthoproteic reaction, a distinctly positive test is obtained, though not as intense as with an egg-white solution of the same nitrogen concentration.

The reduced sulphur reaction is negative, but so is egg-white solution of the same nitrogen concentration.

In the Millon reaction a precipitate is formed that does not turn red on heating.

Trichloracetic and picric acids do not give precipitates, while tungstic and phosphotungstic acids do.

Sodium tungstate and sodium bicarbonate are not protein precipitants as such.

Mercuric salts give definite precipitation.

These statements do not mean that we believe the active agent in pollen extracts to be a protein. The recent work of Grove and Coca (*J. Immunology,* 1925) is quite definite, though not absolutely conclusive, on this point. If one is acquainted with the difficulties encountered by investigators working on the isolation of the active principles of insulin and pituitary extracts, one will understand the practical impossibility of stating that a substance is nonprotein until the active substance has been isolated as a pure material. Actual isolation as a pure material and determination of molecular weight with analysis of the elements present is the only absolute criterion on this point.

GORDON A. ALLES, M.S., Los Angeles.

[The letter of Dr. Alles was referred to Dr. Black, who replies:]

To the Editor:—It seems to me that Dr. Alles has missed the intent of our report. We are not contending that our pollen extract was protein-free in the absolute sense of the word. We found that a pollen extract after a year's time gives no reaction to tests that were previously positive. We felt that this indicated a very definite quantitative change in the protein content and justified the statement made—that the extract contained no protein "so far as may be determined by the ordinary qualitative tests."

With this extract we obtained results as good as those obtained by use of extracts containing considerable quantities of protein. We felt justified in believing, therefore, that this was another indication that quantitative reduction—if not absolute elimination—of protein had no effect on the active substance in pollen extracts.

J. H. BLACK, M.D., Dallas, Texas.

"REACTION OF NORMAL PERSON TO TUBERCULIN"

To the Editor:—My attention has been called to the answer in reply to the question on the reaction of the normal person to tuberculin (THE JOURNAL, February 6, p. 437). To me this answer is most unsatisfactory and misleading and has only added confusion, without in the least giving the desired information. The quotation from Koch (*Deutsche med. Wchnschr.* **16**:1029, 1890) is quite correct, but based purely on clinical observation some thirty-six years ago, long before the specificity or the mechanism of the reaction had been determined.

As might be anticipated, the specificity was first studied in the lower animals, particularly cattle, by such investigators as Frankel, Voges, Kuhnan, Bang and von Behring. The tuberculin test in cattle gave a positive or negative result, corresponding to the presence or absence of tuberculosis as determined by necropsy. In the human being, identical findings have been demonstrated by the anatomic studies of Lebert, Ballenger, Schleuker, Nägeli and Burkhardt, and the diagnostic application of tuberculin by Hamburger, Fraenkel, Franz, Beck and many others.

With the great mass of accumulated data and the generally accepted specificity of the tuberculin reaction, a positive indicating the presence of and a negative an absence of a tuberculous infection, we may return to the original question. It will be observed that the question specifies "in a person who has no tuberculous infection of any kind." Under such conditions, *no* reaction of any kind would be obtained, no matter what amount of tuberculin is employed, unless the dose should be repeated after a hypersensitiveness has developed and then the reaction is interpreted on the basis of a foreign protein and not the presence of a tuberculous lesion.

The distinction between a healthy individual without *any* tuberculous lesion and one clinically healthy, perhaps in excellent health, but with an old tuberculous lesion is an entirely different problem. Information is requested as to dosage of tuberculin to produce a reaction. This has been answered so far as the individual entirely free from a tuber-

"POLLEN THERAPY WITH PROTEIN-FREE EXTRACTS"

To the Editor:—The article by Black and Moore (THE JOURNAL, January 30) contains statements that are distinctly inaccurate and misleading.

F. W. Heyl (*J. Am. Chem. Soc.* **39**:1470, 1917) found that ragweed pollen used in his work contained 4.99 per cent of total nitrogen, of which 2.6 per cent was soluble in aqueous saline solution. Of this 2.6 per cent, from 0.6 to 0.8 per cent was protein in nature, part being albumin and proteose.

H. L. Huber and K. K. Koessler (*Arch. Int. Med.* **36**:751 [Dec.] 1925) obtained solutions of ragweed pollen (1:10, or 10 per cent) which contained 1.54 and 1.61 mg. of nitrogen per cubic centimeter. According to Heyl's figures, these 10 per cent solutions would contain about 0.5 mg. of protein nitrogen per cubic centimeter, or about 3 mg. of pollen protein per cubic centimeter.

Glycerol and water have similar solvent properties. With regard to the nitrogenous constituents of *Artemisia* pollens, we have confirmed this general fact in that we find that glycerol-water-salt extracts and water-salt extracts of the same pollen concentrations contain identical amounts of nitrogen.

Various conditions may modify the usual qualitative protein tests, so that the failure to secure positive tests as Black did is not definite proof of the absence of protein. Further, it usually is considered most probable that protein is present in unpurified biologic extracts containing nitrogen (especially large amounts).

With especial regard to the testing of glycerol solutions of *Ambrosia trifida* pollen, we find the following:

A 2 per cent solution of pollen in 50 per cent glycerol-physiologic sodium chloride solution was used. It contains about 0.3 mg. of nitrogen per cubic centimeter.

In the biuret test, the color of the solution interferes with the recognition of the test. Reducing substances are present which render testing impossible, owing to the rapid reduction of the cupric ion in the alkaline solution.

The Adamkiewicz reaction is negative, but it is also negative with an egg-white solution in 50 per cent glycerol that contained 0.32 mg. of nitrogen per cubic centimeter.

In the Liebermann reaction, a slight red coloration occurs. This test is not definite.

In the xanthoproteic reaction, a distinctly positive test is obtained, though not as intense as with an egg-white solution of the same nitrogen concentration.

The reduced sulphur reaction is negative, but so is egg-white solution of the same nitrogen concentration.

In the Millon reaction a precipitate is formed that does not turn red on heating.

Trichloracetic and picric acids do not give precipitates, while tungstic and phosphotungstic acids do.

Sodium tungstate and sodium bicarbonate are not protein precipitants as such.

Mercuric salts give definite precipitation.

These statements do not mean that we believe the active agent in pollen extracts to be a protein. The recent work of Grove and Coca (*J. Immunology*, 1925) is quite definite, though not absolutely conclusive, on this point. If one is acquainted with the difficulties encountered by investigators working on the isolation of the active principles of insulin and pituitary extracts, one will understand the practical impossibility of stating that a substance is nonprotein until the active substance has been isolated as a pure material. Actual isolation as a pure material and determination of molecular weight with analysis of the elements present is the only absolute criterion on this point.

GORDON A. ALLES, M.S., Los Angeles.

[The letter of Dr. Alles was referred to Dr. Black, who replies:]

To the Editor:—It seems to me that Dr. Alles has missed the intent of our report. We are not contending that our pollen extract was protein-free in the absolute sense of the word. We found that a pollen extract after a year's time gives no reaction to tests that were previously positive. We felt that this indicated a very definite quantitative change in the protein content and justified the statement made—that the extract contained no protein "so far as may be determined by the ordinary qualitative tests."

With this extract we obtained results as good as those obtained by use of extracts containing considerable quantities of protein. We felt justified in believing, therefore, that this was another indication that quantitative reduction—if not absolute elimination—of protein had no effect on the active substance in pollen extracts.

J. H. BLACK, M.D., Dallas, Texas.

"REACTION OF NORMAL PERSON TO TUBERCULIN"

To the Editor:—My attention has been called to the answer in reply to the question on the reaction of the normal person to tuberculin (THE JOURNAL, February 6, p. 437). To me this answer is most unsatisfactory and misleading and has only added confusion, without in the least giving the desired information. The quotation from Koch (*Deutsche med. Wchnschr.* **16**:1029, 1890) is quite correct, but based purely on clinical observation some thirty-six years ago, long before the specificity or the mechanism of the reaction had been determined.

As might be anticipated, the specificity was first studied in the lower animals, particularly cattle, by such investigators as Frankel, Voges, Kuhnan, Bang and von Behring. The tuberculin test in cattle gave a positive or negative result, corresponding to the presence or absence of tuberculosis as determined by necropsy. In the human being, identical findings have been demonstrated by the anatomic studies of Lebert, Ballenger, Schleuker, Nägeli and Burkhardt, and the diagnostic application of tuberculin by Hamburger, Fraenkel, Franz, Beck and many others.

With the great mass of accumulated data and the generally accepted specificity of the tuberculin reaction, a positive indicating the presence of and a negative an absence of a tuberculous infection, we may return to the original question. It will be observed that the question specifies "in a person who has no tuberculous infection of any kind." Under such conditions, *no* reaction of any kind would be obtained, no matter what amount of tuberculin is employed, unless the dose should be repeated after a hypersensitiveness has developed and then the reaction is interpreted on the basis of a foreign protein and not the presence of a tuberculous lesion.

The distinction between a healthy individual without *any* tuberculous lesion and one clinically healthy, perhaps in excellent health, but with an old tuberculous lesion is an entirely different problem. Information is requested as to dosage of tuberculin to produce a reaction. This has been answered so far as the individual entirely free from a tuberculous lesion is concerned, but in the apparently healthy or suspect, the diagnostic dose will vary according to the individual authority, as there is no fixed rule. Koch directed that 1 mg., then 5, then 10 be given, and, if no reaction occurred, to repeat the last dose. This is still followed by some clinicians, while others advise smaller or even larger amounts, preferably a single injection, in order to avoid confusion due to protein hypersensitiveness.

The second paragraph in the answer, the quotation from Tice's Practice, is quite superfluous and unnecessary as it refers to the therapeutic use of tuberculin, which is not requested.

Frederick Tice, M.D., Chicago.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PERFORATING ULCER OF THE FOOT

To the Editor:—Please give me the best treatment of perforating ulcer of the foot on the walking side of the heel. The ulcer is of the size of a half-dollar, dark and round, with surrounding skin elevated. It peeled two or three times, and now is back again rotting like gangrene. If you think that it is not a perforating ulcer, please tell me. Please withhold the name in publishing.

M.D., Mexico.

Answer.—Perforating ulcer of the foot was first described by the French; and from the time Nelaton published his paper in 1852, the French literature has contained many articles on the condition. For this reason it is usually referred to under the French name mal perforant du pied.

Poncet, in 1872, was the first to recognize the relation of the condition to disease of the nervous system, and it was shortly after this that the relationship between diseases of the spinal cord, particularly tabes, and perforating ulcer of the foot was established. It is now well established that it may result from several very different causes.

It occurs chiefly in males, usually in men over 40 years of age. It is very rare in the young, but two cases have been reported in children. It occurs almost always in working people who are on their feet a great deal, and the ulcer (or ulcers—for there may be two or even three) occurs at points of pressure on the plantar surface of the foot. The three points where the ulcer occurs are, in order of frequency, beneath the metatarsophalangeal articulation of the great toe, beneath the fifth toe, and beneath the heel.

While pressure and trauma unquestionably are important in determining the site and development of the ulcer, these mechanical factors are only contributory and are not the underlying cause. Today it is generally accepted that the chief factor is some change in the nervous system. The underlying nervous lesion may be located in the central nervous system or in the peripheral nervous system. It results in sensory, vasomotor and trophic changes which may affect the nerves of the entire limb or be limited to the portion of the nerves immediately in the vicinity of the ulcer. Among the types and causes of peripheral neuritis that may lead to the development of a perforating ulcer are traumatic neuritis irrespective of the nature of the trauma, tumors of nerves, tumors that press on the nerves, pressure on the nerves by callus, alcoholic neuritis, neuritis following freezing or burns, and the neuritis of leprosy. The anesthesia present seems particularly to favor the development of a perforating ulcer. Changes in the central nervous system, particularly tabes dorsalis, apparently are of greater importance. Other important causes are: injury to the cord due to fractures of the vertebrae, tumors of the cord, spina bifida, with its associated cord changes, and syringomyelia. Other less frequent causes are: paresis, progressive muscular atrophy, amyotrophic lateral sclerosis, and spastic spinal paralysis. Although typical perforating ulcers of the foot have been reported in diabetes, the typical diabetic ulcer is usually painful, whereas the typical mal perforant is characterized, as a rule, by the entire absence of any pain.

Treatment includes not only the local condition, but, wherever possible, the underlying causal condition as well, as in alcoholic neuritis and in syphilis. This is particularly important in peripheral nerve lesions.

Methods of local treatment that have been reported by various authors as having produced benefit in certain cases are the use of constant and induced electric currents, roentgen-ray treatment locally; high frequency currents; hot-air treatment, and nerve stretching. It is important to keep the patient in bed, i. e., off of his feet, and the ulcer must be dressed aseptically and kept surgically clean.

Lasting results can be achieved only by surgical intervention. In cases in which no communication exists between the ulcer and the neighboring bone or joint, careful and complete excision of the ulcer, going well into the healthy tissue, is all that is required. This can usually be done without the use of any anesthetic, as there is usually total anesthesia of the tissues about the ulcer. If the ulcer is very superficial, it may suffice to excise merely the thickened epidermis that forms the margin of the ulcer. But it is best to dissect off the floor of the ulcer in order to determine whether there is not a communication with the adjacent joint. For this reason it is best to operate with a constrictor applied. In case one finds that the ulcer communicates with the joint or bone, all destroyed bone should be removed in order to guard against a recurrence. And even with the best local treatment, recurrences are frequent. After the ulcer has been completely cut out, well into normal tissues, the defect fil[illegible] After the wound has healed, this area is [illegible] by wearing a large bunion plaster to keep pressure off this part of the foot.

Occasionally, secondary infection of so extensive a nature develops as to threaten the patient's life. Here more radical operations are required. It is only rarely, however, that amputation is indicated. Amputation is most often indicated when the ulcer is due to a lesion of the central nervous system, as tabes, paresis or syringomyelia; for in these conditions simple excision is of little avail and is usually followed by recurrence. One may first do a low amputation; but if a low amputation is followed by a recurrence, it is probably advisable to do the second amputation at once high up through the thigh.

PREMENSTRUAL RISE IN TEMPERATURE IN TUBERCULOSIS

To the Editor:—Can you tell me the cause and the significance of the premenstrual rise in temperature in women with tuberculosis of the lungs? Should this disappear as the case becomes arrested and goes on to an apparent cure? Is a premenstrual rise in temperature found in normal, healthy women? Kindly omit name.

M.D., Washington, D. C.

Answer.—Belfield found in the examination of a series of women who were in apparently normal health that there was a slight premenstrual rise in temperature. It is not the practice ordinarily to take, as a routine, daily temperatures of people in apparently normal health. It is only when a patient goes to an institution, such as a tuberculosis sanatorium, that the routine taking of temperatures is established, and in taking this routine temperature it becomes evident that many women have a definite premenstrual rise in temperature. There is no known reason for this temperature disturbance, but it is thought that the so-called internal secretions are in some way responsible. While this phenomenon has been observed for a great many years, there is no special significance attached to it.

PARALYTIC ILEUS AND LOCAL ANESTHESIA

To the Editor:—I operated on a patient a few weeks ago, under local anesthesia, for a double inguinal hernia. I used 3½ ounces (100 cc.) of 1 per cent solution of procaine. The sacs of each hernia were empty at the time of the operation. About thirty-six hours following the operation, he developed a paralytic ileus which proved fatal at the end of the thirty-six hours. Do you know of a similar case, and do you know of any reference that might give me some pertinent information?

M.D., Neb.

Answer.—Two questions seem to be involved in the discussion of the death of the patient following operation with local anesthesia for double inguinal hernia—the pharmacology of procaine and the surgical problem.

The pharmacology of procaine does not lend any support to the view that it caused paralytic ileus after thirty-six hours, because it is eliminated rapidly after it enters the blood stream, and with care in injection little of the procaine could come into direct contact with the intestine.

It seems impossible to express any definite opinion, unless the preoperative history and the necropsy findings are given. No cases are recorded in which 1 Gm. of procaine given subcutaneously caused paralytic symptoms in the intestinal tract.

TREATMENT OF SNAKE BITE

To the Editor:—The season is approaching when, in this region, there are frequent snake bites. Several of my patients have been inquiring what is the best immediate treatment for this condition. Before the patient can get medical help or a physician can reach the patient, sometimes five or six hours elapse, because of distance, poor transportation, or lack of telephone service. One of the practitioners here has been advocating the following immediate treatment: (1) arrest of circulation, ligating with strap or cord; (2) sucking freely to withdraw poison; (3) rubbing over wound and round it with a few drops of petroleum containing iodine (this for pain); (4) covering of wound with bandage; (5) saturation of bandage with potassium permanganate solution; (6) liberal doses of whisky; (7) medical attention. He advocates the same measures for dog bite. Please let me know whether these instructions (regarding application of petroleum with iodin crystals, and the application of potassium permanganate solution) have any effect to retard the spreading of poison. Have they any value at all? Do you agree in sucking the wound? Could you suggest a better or a satisfactory immediate treatment?

V. P. Bell, M.D., Conway, S. C.

Answer.—The first indication in the treatment of snake bite is to prevent the absorption of the poison. This should be attained by application of a stasis bandage proximally to the bite for from twenty to thirty minutes. After this, it should be loosened gradually and for a short time at intervals so as to permit the most gradual absorption possible while maintaining sufficient circulation in the limb to avoid injury from constriction.

Sucking the wound is commonly the next thing recommended, and as the poison is relatively harmless to the unbroken mucous membrane, there can be no serious objection to it. It is better, however, to enlarge the wound by an X shaped incision about a quarter of an inch deep. Iodine, whether in the form of tincture or of petroleum solution, might be used as an antiseptic before incision, as well as for its destructive action on venom. The wound should now be made to bleed freely by squeezing and washing. For the destruction of the venom, potassium permanganate crystals rubbed into the wound and a 2 per cent solution of it injected into and around the wound are particularly recommended. To saturate the bandage with potassium permanganate solution may be likewise useful.

The third most important step is the injection of antivenom serum specific of the poison under treatment.

The time honored free libations of whisky even to the point of drunkenness is of doubtful value; and it is possible that some deaths after snake bite have to be ascribed to the reckless use of this "remedy." Stimulation by strychnine and by aromatic spirit of ammonia, if required, is more rational.

Most important is the prevention of snake bites by extermination of venomous snakes and protecting their natural enemies, as well as by wearing strong shoes and leather leggings when going through thickets and by refraining from handling snakes.

VAGINAL SMEARS AND SANITATION OF SWIMMING POOLS

To the Editor:—Kindly express your opinion as to the advisability or inadvisability of taking vaginal smears from applicants to the swimming pool of Y. W. C. A. organizations. State also reasons for your opinions. Please omit my name.

M.D., D. C.

Answer.—The routine taking of vaginal smears from women using swimming pools appears to be something of an open question. A number of colleges do it and it is probably advisable if one wishes to take every possible precaution. Seemingly there is no record of any infection from the gonococcus through the medium of swimming pools in this country. This organism is short lived in air or water.

EFFECTS OF MERCURIC CHLORIDE

To the Editor:—1. What is the shortest length of time between the taking of mercuric chloride as a poison and death? 2. What are the colors of the tissues after taking mercuric chloride? 3. What kind of a preservative is it? 4. Does it make any difference in what form it is taken?

F. F. Blair, M.D., Montgomery, Ala.

Answer.—1. Death from mercuric chloride poisoning may occur in half an hour from shock, but commonly life is prolonged for from two to four days, and it may last into the second week.

2. Some parts of the alimentary canal are sure to show inflammatory changes. Patches of congestion and erosion appear in the mouth, throat, stomach or intestines. The kidneys swell and become acutely inflamed.

3. It is used by taxidermists to preserve skins and mounted preparations.

4. Theoretically, mercuric chloride would be both more quickly and more surely fatal if ingested in solution. Actually, at the present time most of the tablets of mercuric chloride are made so that they will be quickly soluble. Practically, then, there is little difference whether the mercuric chloride is taken in solution or in tablet form.

Medical Education, Registration and Hospital Service

COMING EXAMINATIONS

American Board of Otolaryngology, Texas: Dallas, April 19,

California. San Francisco, April 27. Sec., Dr. H. W. Loeb, 1402 South Grand Boulevard, St. Louis, Mo.

Arkansas Little Rock, May 11-12. Sec, Dr. J. W. Walker, Fayetteville. Homeo Board, Little Rock, May 11. Sec., Dr. A. A. Pringle, Eureka Springs Eclectic Board, Little Rock, May 11. Sec., Dr. Claude E. Laws, Fort Smith

District of Columbia April 13. Sec., Dr. Edgar P. Copeland, 1801 Eye St, Washington, D C.

Georgia Atlanta, June 9-11; Augusta, June 1-3. Sec., Dr. C. T. Nolan, Marietta, Ga

Hawaii: Honolulu, April 12-15. Sec., A. L. Davis, 1254 Emma Street, Honolulu.

National Board of Medical Examiners: Part I, June 21-23; Part II, June 22 23. All applications should be made on or before May 15. Sec., Dr. J. S. Rodman, 1600 Walnut Street, Philadelphia.

Nevada: Carson City, May 3. Sec., Dr. Simon L. Lee, Carson City.

New Mexico: Santa Fe, April 12-13. Sec., Dr. W. T. Joyner, Roswell.

North Dakota January Examination

Dr. G M. Williamson, secretary of the North Dakota Board of Medical Examiners, reports the oral, written and practical examination held at Grand Forks, Jan. 5-8, 1926. The examination covered 13 subjects and included 100 questions. An average of 75 per cent was required to pass. Of the 10 candidates examined, 8 passed and 2 failed. Three were licensed by reciprocity and 1 by endorsement of credentials. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent
Rush Medical College	(1925)	79
Harvard Medical College	(1923)	86
University of Minnesota Medical School	(1924) 81, (1925)	88
University of Manitoba Faculty of Medicine	(1921)	86, (1924) 76, 79, (1925) 83

FAILED

Book Notices

Gynecologic Urology. By Lynn Lyle Fulkerson, A.B., M.D., F.A.C.S., Assistant Professor of Gynecology, New York Post-Graduate Medical School. Cloth. Price, $6. Pp. 247, with 166 illustrations. Philadelphia: P. Blakiston's Son & Co., 1925.

The preface states that the book is devoted to the technic of endoscopy and cystoscopy in the female, and the diagnosis and treatment of the more common diseases of the urologic tract, and suggests that the intention of writing it was to enable students to acquire quickly a working knowledge of the subject. This has been accomplished for the most part in a satisfactory manner. Many of the paragraphs are extremely brief but are not misleading. In several instances the expressions used are somewhat inaccurate; for example, on page 18 under the paragraph headed edema, the statement that "the term should be applied whenever the blood vessels have disappeared because of swelling" is, of course, not accurate. The recommendation "that the bladder should be irrigated at least once a day with warm saline or 4 per cent boric solution" in the treatment of acute cystitis (page 55) would probably not receive general approval. Again, on page 57, "If the cystitis does not respond to treatment and always if known pyelitis exists, the ureters should be catheterized every one to five days and kidney lavage with instillation of 5 cc. of 1 per cent silver nitrate done" seems an unduly vigorous method of treatment to recommend as a routine. The technic of cystoscopic examination is excellently explained. The recent work on nephritis and nephrosis is outlined in chapter VIII, and that on renal function tests in chapter X. The illustrations are partially original and are, for the most part, satisfactory; however, they do not all measure up to the standard set by the majority. The book as a whole contains a great deal of information in a brief form and will serve to stimulate the physician or surgeon who sees a large number of women patients to examine carefully the urinary tract in an intelligent manner. As a whole, the book is a good one for the student, and supplements the standard works in gynecology.

Les fondements biologiques de la psychologie. Par Jean Lhermitte, Professeur agrégé de psychiatrie à la Faculté de médecine de Paris. Paper. Price, 14 francs. Pp. 241, Paris: Gauthier-Villars et Cie, 1925.

In a brief introduction it is shown that even two thousand years ago the idea of considering the brain merely as a storehouse for images was held and discarded, and the realization expressed that to arrive at facts of sufficient solidarity to uphold theories one must go beyond introspection to anatomic, physiologic and clinical observation of the brain. A brief but adequate historical review brings the placement of psychic activity in the brain to date.

The work is divided into eight chapters: 1. The structure of the nerve cell and fiber; the nerve impulse, its nature and action in cell, fiber and brain. 2. The phylogenetic development of the nervous system. Subheads: stage of appearance of, general irritability, of specialized receptors, of reflexes, of intersegmental reflexes, of suprasegmental neurons. The results of suprathalamic and infrathalamic decerebration in fish, amphibians, reptiles, birds and mammalians. The complexity of structure and conduct in the mammalian makes categorical conclusions impossible. 3. Ontogenesis: the structure and physiology of the nervous system of the fetus and of the infant. The cortex plays little if any part in the life of the fetus; movement is of the order of the reflex. Flechsig's claim of centers of projection versus centers of association is denied, but insight into the relation of function to structure is gained as a result of Flechsig's work. As the relations in the brain become more complex, conduct becomes less uniform and reflex and more individual. Anencephaly in man shows failure of development with more striking lack of function than does decerebration in dog and monkey; hence the greater relative importance of the cortex in man. 4. The structure and physiology of the cortex and corpus striatum. The relations of the midbrain to the sympathetic system and of the cortex to vegetative life. 5. The known relations between physical manifestations of emotions and brain anatomy: optic thalamus, lenticular nucleus and bulbopontile nuclei. There are cortical centers for emotions also. If cortical control is lost, emotion is expressed irrespective of thought; when the thalamus is cut off from the lower centers there is no outward expression of emotion. 6. Disturbances of language: comprehension and expression (exclusive of pure motor failure). Aphasia: of reception (sensory), of expression (motor), global. Word deafness, word blindness, pure motor aphasia and agraphia. Aphasia is not a destruction of brain entities: images of words, but rather of "l'intelligence" of the language. Verbal images are not static but dynamic. Musical language: tone and rhythm more primitive than articulated words; hence may persist though the latter are destroyed. Amusia, like aphasia, presents a variety of pictures. The assumption that the differences are due to focal distructions of different areas seems rather forced. 7. Center for the regulation of the states of waking and sleeping ventral to the third ventricle and extending downward below the aqueduct of Sylvius. This center is susceptible to the secretions of the endocrine system and also to cortical impulses. The relation of thinking to states of sleeping and waking: thinking not a matter of exclusive cortical activity. 8. Regulating center of activity of thought and psychomotor expression in the parencephalon.

This is an eminently serviceable book. There is a satisfactory absence of explanations of abstractions by the use of further abstractions. The anatomic and physiologic statements are nicely correlated and the direction of further moves of inquiry clearly indicated. Some such work as this should be a part of the equipment of every student of medicine.

The Clinical Study and Treatment of Sick Children. By John Thomson, M.D., LL.D., F.R.C.P., Consulting Physician to the Royal Edinburgh Hospital for Sick Children. Fourth edition. Cloth. Price, 30 shillings net. Pp. 912, with 258 illustrations. Edinburgh: Oliver and Boyd, 1925.

The usefulness of this book has been greatly enhanced in this edition. Much material of value and interest has been added. New sections have been introduced on the home care of blind, deaf and crippled children, exudative diathesis, and erythredema, as well as a discussion of minor subjects such as cephalic bruits, pyknolepsy and hypertelorism, recently described by Grieg. Throughout, little is said about pathology, so that the author has been able to devote more space to clinical methods, symptoms and descriptions of those diseases which are peculiar to children and show characteristic symptoms when they occur in early life. A valuable feature of the text lies in the references given to the papers in the periodical literature, from which the author has drawn many facts and suggestions. The portions on the examination of the child, the skin, the nervous system, and the functional nervous disorders are well written and very complete. The chapter on the teeth is exceptionally inclusive for a book of this type. On the other hand, little mention is made of the acute infectious diseases of childhood, including the exanthems, except for a page or two in the appendix devoted to the consideration of the periods of incubation. On the whole, the practitioner as well as the student will find much information of interest in this book.

Das Augenzittern als Gehirnstrahlung. Ein Atlas der Augenzitternkurven. Von Prof. Dr. Johannes Ohm, Augenarzt in Bottrop. Paper. Price, 21 marks. Pp. 326, with 266 illustrations. Berlin: Urban & Schwarzenberg, 1925.

A highly technical scientific book that starts with a quotation from Goethe and closes with a measure of the Fifth Symphony of Beethoven is somewhat unusual. The motif of the book is introduced poetically: "In the darkest castle of the Westphalian earth lie inflammable stones that represent the remains of majestic prehistoric forests, grown under the rays of a tropical sun. Recovery of the stones is accompanied by death, mutilation and manifold diseases, among the most peculiar of which is the miner's nystagmus." This motif is elaborated in the woodwinds by an analysis of the graphic curves of some 150 cases of nystagmus, recorded with the different instruments that have been developed by the author.

A subdivision of the thema shows three main types of nystagmus:

- A. Reflex nystagmus.
  - 1. Optical source.
  - 2. Vestibular source.
  - 3. Sensory source.
- B. Central nystagmus.
  - 1. From the region of Deiters' nucleus.
  - 2. From the central optic radiations.
  - 3. From the cortical motor centers.
- C. Nystagmus retractorius and protractorius.

The divisions of the thema are worked over in extenso and then reassembled in a fairly brief recapitulation. The concerto closes with an elaborate coda in the usual form. For one vitally interested in nystagmus, the book contains a wealth of information, both original and bibliographic. But for one whose interests lie in other directions, the book must be classed as an excellent soporific, far superior to the time-honored method of counting sheep.

Ears and the Man. Studies in Social Work for the Deafened. By Annetta W. Peck, Estelle E. Samuelson and Ann Lehman. With an introduction by Wendell C. Phillips, M.D., President-Elect of the American Medical Association. Cloth. Price, $2 net. Pp. 217. Philadelphia: F. A. Davis Company, 1926.

The three authoresses, themselves deaf, are, according to Dr. Phillips, the first of their profession to enter the new field of social work for the deafened. Their full sympathy therefore goes to those unfortunately afflicted with defective hearing. They consider the different aids offered the hard of hearing, not only from a social standpoint, but also from that of their economic struggle. For the hard of hearing, the reading of this book will bring much information and encouragement. To those who are desirous of helping the unfortunate deaf, it will offer many suggestions and much information.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

The Evolution of Orthopaedic Surgery. By Robert Bayley Osgood, A.B., M.D., John B. and Buckminster Brown Professor of Orthopaedic Surgery in Harvard University. First Detroit Orthopaedic Lecture. Auspices of the Wayne County Medical Society, Detroit, Michigan. March 16, 1925. Cloth. Pp. 70, with 49 illustrations. St. Louis: C. V. Mosby Company, 1925.

Beautifully prepared history of orthopedic surgery, based on biographic method.

Die Chirurgie. Eine zusammenfassende Darstellung der allgemeinen und der speziellen Chirurgie. Herausgegeben von Prof. Dr. M. Kirschner und Prof. Dr. O. Nordmann. Lieferung 6, IV. Band. Die Chirurgie der Mundhöhle, der Speicheldrüsen und des Rachens. Von Prof. Dr. F. Brüning. Die Chirurgie des Kehlkopfes und der Luftröhre. Von Prof. Dr. J. Soerensen. Paper. Pp. 358, with illustrations. Berlin: Urban & Schwarzenberg, 1925.

Additional part of new German system of surgery.

La pratique des déviations vertébrales: (scoliose—cyphose—lordose). Par Carle Roederer, Assistant d'orthopédie a l'Hôpital Saint-Louis, et René Ledent, Directeur des cours d'éducation physique à Liége. Paper. Price, 42 francs net. Pp. 376, with 215 illustrations. Paris: G. Doin & Cie, 1926.

An orthopedic consideration of spinal curvatures, printed shabbily on miserable paper.

Éléments de microbiologie générale et d'immunologie. Morphologie et physiologie des microbes pathologie générale des infections microbiennes. Par M. Nicolle, Professeur a l'Institut Pasteur. Second edition reviewed by A. Boquet. Paper. Price, 35 francs net. Pp. 358. Paris: G. Doin & Cie, 1926.

A French textbook poorly printed and without illustrations.

Individual Gymnastics. A Handbook of Corrective and Remedial Gymnastics. By Lillian Curtis Drew, Director of Department of Corrective Gymnastics, Central Branch Y. W. C. A., New York City. Third edition. Cloth. Price, $2.25. Pp. 276, with 121 illustrations. Philadelphia: Lea & Febiger, 1926.

Popular manual by well trained and experienced teacher.

Hysteria By Ernst Kretschmer, M. D., A. O. Professor of Neurology and Psychiatry in Tubingen. Translated by Oswald H. Boltz, M.D., Senior Assistant Physician in the Manhattan State Hospital in New York City. Nervous and Mental Disease Monograph Series, No. 44. Pp. 120. New York: Nervous & Mental Disease Publishing Company, 1926.

Study of whole subject, attempting to correlate work of Kraepelin and of Freud.

The Nematode Parasites of Vertebrates. By Warrington Yorke, M.D., Professor of Parasitology, University of Liverpool and Liverpool School of Tropical Medicine, and P. A. Maplestone, M.D., D.S.O. With a foreword by C. W. Stiles, Professor of Zoology, United States Public Health Service. Cloth. Price, $9. Pp. 536, with 307 illustrations. Philadelphia. P. Blakiston's Son & Co., 1926.

Technical work for special students and experts.

The Natural Increase of Mankind. By J. Shirley Sweeney, M.A., M.D., D.Sc. Cloth. Price, $4. Pp. 185. Baltimore: Williams & Wilkins Company, 1926.

Scientific consideration of birth rates, with a hopeful outlook for birth control, recognizing the existence of differential fertility.

Indigestion: What It Is and How to Prevent It. By Arthur L. Holland, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical College. Cloth. Price, $1.25. Pp. 130, with 12 illustrations. New York: D. Appleton & Co., 1926.

Popular treatise, well written and, like few others in its field, free from faddism.

Précis de bactériologie pratique. Par Jules Courtmont, Professeur d'hygiène à la Faculté de médecine de Lyon, Médecin des hôpitaux. Fifth edition by Paul Courtmont. Cloth. Price, 85 francs. Pp. 1259, with illustrations. Paris: G. Doin & Cie, 1926.

Well illustrated but poorly printed popular French textbook of bacteriology.

Die Ursache des Carcinoms. Von Prof. R. P. Van Calcar. Aus dem bacteriologisch-hygienischen Laboratorium der Universität Leiden. Paper. Pp. 66, with 45 illustrations. Leiden: S. C. Van Doesburgh, 1926.

General consideration of the causes of cancer, leading to no practical conclusion.

A Manual of Clinical Laboratory Methods. By Clyde Lottridge Cummer, Ph.B., M.D., Associate Professor of Clinical Pathology, School of Medicine, Western Reserve University. Second edition. Cloth. Price, $6.50. Pp. 547, with 181 illustrations. Philadelphia: Lea & Febiger, 1926.

New edition brought quite up to date.

Das Wachstum des Kindes. Von Prof. Dr. Eugen Schlesinger, Stadtischer Fursorgearzt in Frankfurt a. M. Paper. Price, 6 marks. Pp. 128, with 8 illustrations. Berlin: Julius Springer, 1926.

Studies of height and weight of children, and various influences affecting them.

The History of Small-Pox in Australia, 1909-1923. By J. H. L. Cumpston, M.D., D.P.H., Director-General of Health and Director of Quarantine, and F. McCallum, M.B., B.S., D.P.H., Quarantine Officer, Commonwealth Department of Health. Commonwealth of Australia Department of Health. Service Publication No. 29. Paper. Pp. 243. Melbourne, 1925.

An Investigation into the Statistics of Cancer in Different Trades and Professions. By Matthew Young, M.D., and W. T. Russell, with the collaboration of John Brownlee, M.D., D.S., and E. L. Collis, M.D. Medical Research Council. Special Report Series, No. 99. Paper. Price, 1 shilling, 6 pence net. Pp. 50. London, 1926.

A Cholesterinemia e suas Relações com a Leucocytose (Cadeira de Clinica Medica). Por Dr. Carlos Bento. These apresentada á Faculdade de Medicina de Porto Alegre em 30 de Novembro de 1925 e defendida em 23 de Dezembro do mesmo anno. Pp. 98 with illustrations. Porto Alegre, 1925.

Jahresbericht der Abteilung Volkswohlfahrt und Landwirtschaft der Regierungskommission des Saargebietes. 1924.

Miscellany

NEW WORK ON VITAMINS

At the London Royal Society of Medicine, some new work on vitamins with important practical applications has recently been described by Prof. R. H. A. Plimmer, who discussed the relation of the quantity of vitamin B to the quantity of food. He described experiments conduced to determine how much vitamin B was needed to maintain health, and how this quantity was affected by alterations in the total quantity of fats, carbohydrates and proteins in the diet. Chickens were fed on a diet of rice and fish meal with cod liver oil and yeast extract as the sources of vitamins A and B, respectively. It was found that 8.6 per cent of yeast extract was needed to maintain health on a basal diet containing 5 parts of fish meal, but that when the protein in the diet was increased by raising the fish meal to 30 parts, deficiency symptoms appeared, the most striking of which were deficient bone formation and bow legs. These and other similar experiments proved that, when the protein of the diet was increased, the vitamin B supply also needed to be increased to maintain health. There were differences in the vitamin B requirements of animals. The amount of yeast extract needed in the diet by different animals was, approximately: fowls, 12 per cent; pigeons, 8 per cent; rats, 4 per cent; cats, more than 4 per cent. These figures suggested that man probably required a vitamin B supply equivalent to about 8 per cent of yeast extract in the diet, and showed that the vitamin requirement of an individual had a constant ratio to the total food taken. One of the chief effects of a partial deficiency of vitamin B was intestinal stasis, which resulted in retention of putrid food residues and absorption of products of putrefaction. McCarrison had noted this intestinal effect as a preliminary stage in the production of polyneuritis in pigeons deprived completely of vitamin B. In the experiments described in which there was only partial lack of vitamin B, this stage, which was only a temporary one in the acute experiments, became a chronic condition. Professor Plimmer thought that the fundamental effect of lack of vitamin B was to reduce atony of the intestine, and that polyneuritis was possibly due to absorption of some toxic products of putrefaction. These experiments raised the question as to whether the supply of vitamin B in normal human diets was adequate. He suggested that the ordinary daily diet was seriously deficient in vitamin B, but that the tendency to intestinal atony thus produced was counteracted to some extent by the widespread use of purgatives.

Prof. J. C. Drummond described new facts concerning fat soluble vitamins. The growth promoting fat soluble vitamin A was identified by McCollum in 1913. In 1919, Mellanby showed that the lack of a fat soluble factor was concerned with the production of rickets, and in 1922 McCollum brought forward proof that this antirachitic factor, now called vitamin D, was not vitamin A. Evans, during the last few years, had shown that there was a third fat soluble factor (vitamin E) necessary for reproduction. Professor Drummond said that the vitamins were not mere hypothetic substances, nor even bodies of completely unknown chemical structure, such as the bacterial toxins, but substances concerning whose chemical nature a good deal was already known. He described the fractionation of cod liver oil, and showed that the whole of the fat soluble vitamins were contained in the 1 per cent of nonsaponifiable matter in the oil. Half of the active residue was cholesterol and was inactive. Fractional distillation of the remainder under low pressures showed that the whole of the active portion was contained in the fraction boiling between 180 and 200 C., at a pressure of from 1 to 2 mm. of mercury. This active fraction consisted largely of an unsaturated alcohol. The daily dose of the most active fraction was only 0.002 mg. for a 100 Gm. rat. The recent work on the production of the antirachitic vitamin by ultraviolet rays gave much information as to the chemical nature of the antirachitic vitamin D. The discovery of Steenbock that irradiation of food produced vitamin D had led to the discovery that only oils and fats could thus be activated, and next that only the unsaponifiable matter in fats could be activated. Finally, it was shown that the exposure of chemically pure cholesterol to ultraviolet rays caused the formation of vitamin D. Prolonged exposure of cholesterol to ultraviolet rays produced a semi-solid, waxy material with an intense antirachitic action. This meant that one of the vitamins had been synthesized.

MAN AND THE GREAT APES

At the Royal College of Surgeons, in London, Sir Arthur Keith recently discussed the bearings of the fossil skull discovered near Taungs, South Africa, on current views concerning the origin of man and the ape. He said it was now certain that the skull was that of a young anthropoid ape, cousin to the two existing African anthropoid apes—the gorilla and the chimpanzee. The view originally held by Dart that the discovery had revealed an extinct family of beings which occupied a position intermediate between anthropoids and humanity could no longer be maintained. The geological evidence showed that the skull had been entombed in a limestone bluff during the Pleistocene period, at which time the earlier forms of mankind had already been evolved in other parts of the world. The discovery was important for the light it threw, not on the evolution of man, but on the history of man's nearest living relatives, the great anthropoids of Africa. Hitherto our knowledge of extinct anthropoids had had to be based on fossil fragments of a jaw or on isolated teeth, but in the present instance we had details of face, nose, teeth, skull, and even certain features of the brain. It shared some characters with the chimpanzee, others with the gorilla, while others were peculiar to itself. In size of brain the Taungs anthropoid stood above chimpanzees of its own age, but below gorillas in the fourth year of age, the age reached by the Taungs ape. This fossil ape had a narrow, long brain and head. All living anthropoids had relatively wide brains and heads tending toward roundness, save among gorillas, among which long-headed or dolichocephalic individuals did occur occasionally. Thus, the discovery at Taungs showed that among anthropoid apes there was, just as among human beings, a tendency to the production of dolichocephalic races and brachycephalic races. Changes due to age were most pronounced and brutal in the gorilla. In its cousin, the chimpanzee, there was a tendency to retain the characters of youth. This tendency to carry youthful characters into adult life had played a large part in the evolution of human races. The same tendency was seen in many features of the Taungs skull. Yet that it was destined to pass through stages which would lead on to the full structural status of the anthropoid there could be no doubt. At the time of death its first permanent molar teeth were just cutting the gums. Although the milk teeth were small—as was also the case in young gorillas—the permanent teeth were large. They were much larger than in the chimpanzee, and almost as large as those found in the gorilla. In size of jaw, the Taungs ape must have exceeded the chimpanzee.

The discovery at Taungs threw light on the climate and flora of South Africa during the Pleistocene period. Although baboons could still extract a subsistence on the dry and arid sweeps of Bechuanaland, one could not conceive of anthropoids doing so. The climate need not have been tropical, for the Kivu gorilla, although living near the equator, withstood the wet and cold encountered at an elevation of 10,000 feet. In the Pleistocene period, anthropoid apes extended 2,000 miles farther south in Africa than they did today. We might safely presume that the green and verdant belt of Africa extended an equal distance farther south than it now did, for there was no feature in the Taungs skull which suggested that the manner in which its owner walked and climbed was different from that of the gorilla.

Medicolegal

Skill and Care Required of Surgeons—Evidence

(Bungardt v. Younger (Okla.), 239 Pac. R. 469)

The Supreme Court of Oklahoma, in affirming a judgment in favor of plaintiff Younger, says that, according to his evidence, he was taken to the defendant's hospital to be treated for a broken leg. The tibia was set, a plaster cast applied, and a roentgenogram taken which showed that bone properly set. Shortly afterward the plaintiff began suffering intensely from constant pain near the ankle. He and his parents called the defendant's attention to it and suggested their belief that the fibula also was broken. The defendant assured them it was not. About three weeks after the cast was put on the defendant removed it, made an examination, and pronounced the leg all right. The next day, on further insistence by the parents, the defendant said that another roentgenogram would be taken, which was done. It showed the fibula broken near the ankle, ends overlapping, and the tibia out of apposition. The defendant said that the tibia would have to be rebroken and both bones reset, and advised the application of a Lane plate to the fracture of the tibia. The operation was performed and the leg again placed in a cast. Roentgenograms subsequently taken showed that after this operation bone absorption commenced in the broken ends of the tibia, resulting in nonunion, weakness and deformity. The plaintiff also proved by several witnesses certain declarations against interest which were said to have been made by the defendant between the time of the first setting of the tibia and that of the Lane-plate operation. The court does not think that there was such a lack of evidence of want of ordinary care and attention as would make the overruling of the defendant's demurrer to the plaintiff's evidence reversible error.

Generally the skill required of surgeons in performing an operation is ordinary skill, and the care required of them in the subsequent treatment of the patient is ordinary care. In actions for negligence in cases of this character, the plaintiff has the burden of proving want of ordinary skill in the performance of the operation or want of ordinary care in the subsequent treatment, and nonsuccess or unsatisfactory results of the operation will not alone establish the essential elements of legal detriment. However, where there is evidence of facts attending the operation or the subsequent treatment which in the ordinary affairs of life would bear a causal relation to the demonstrated result, and those facts are of such a nature as to be comprehensible and understandable to laymen of ordinary intelligence, the probative value of such evidence and the causal relation of such facts to the alleged legal detriment are questions of fact for determination by a jury under proper instructions. In such a case, where expert evidence is required to make out a cause of action, and there is evidence of declarations against interest proved to have been made by the defendant, himself an expert and assuming to treat the plaintiff with ordinary skill and care, which, with all the other facts and circumstances in evidence, tends to show a want of ordinary skill and care in such treatment and to show a causal relation of such want of skill and care with the resultant detriment complained of, such evidence is sufficient, as against a demurrer thereto, to entitle the plaintiff to go to the jury.

Negligence is not predicable on the nonsuccess of a surgical operation when reasonable skill and ordinary care are exercised in its performance, nor is negligence predicable on error of judgment in the method of treatment when ordinary care and intelligence direct such judgment. But if, in the exercise of reasonable skill and ordinary care, it ought to be discovered that an injury or ailment does not yield to the usual and approved method of treatment, the failure to discover this fact, or, if discovered, a failure to acquaint the patient with that fact, will constitute negligence.

Ordinary care is defined by the Oklahoma statute to be such care as persons of ordinary prudence usually exercise about their own affairs of ordinary importance. A want of ordinary care constitutes negligence. Of course, this character of negligence or want of ordinary care cannot be predicated on results obtained, because in that event recovery would be based purely on speculation and conjecture rather than on facts in evidence. A jury would be required to reason backward from the demonstrated result and reach a conclusion as to the causes contributing thereto, which would necessarily be theoretical. But when there is evidence of facts which a jury may grasp and understand and apply thereto a common knowledge and intelligence, the case presented is one of fact and a recovery is not based on speculation and conjecture.

Ordering of Physical Examination of Plaintiff

(Cook v. Miller (Conn.), 130 Atl. R. 571)

The Supreme Court of Errors of Connecticut says that the order of the trial court for an examination of the person of the plaintiff was a proper exercise of discretion. The discretionary right to make such an order would seem to flow legitimately from the right of a defendant to call an injured plaintiff as a witness and compel his testimony as to his injuries, or to cross-examine him relative thereto, if he testifies in his own behalf. While in a large number of states this matter is one of statutory regulation, in the states where no such regulation obtains the decided preponderance of authority favors the right of the trier in his discretion to make such an order. However, in view of the fact that the jury found for the defendant, and the only bearing that a physical examination could have had was as to the amount of damages, if error in this regard had been committed, it would have been harmless.

Issuance and Filling of Prescriptions for Narcotics

(Eckert v. United States (U. S.), 7 Fed. R. (2d) 257)

The United States Circuit Court of Appeals, Eighth Circuit, in reversing a judgment of conviction of defendant Eckert, says that he was a druggist who had registered with the collector of internal revenue as a dealer in the drugs sold. The prosecution took the broad stand that he had violated the Harrison Narcotic Act and was subject to punishment because of the large amount of drugs in the aggregate which he had sold on prescriptions within a given time—approximately the first six months of 1920, during which prescriptions filled by him totaled 228 ounces of morphine and 75 ounces of cocaine, whereas it was testified by a narcotic agent that this far exceeded the average sold by a druggist within the city of St. Louis during that time.

The trial court in its instructions to the jury accepted the theory of the prosecution and charged that the proof as to the great number of prescriptions filled by the defendant during the time selected and the total amount of drugs sold by him in filling them was for the purpose of enabling the jury to reach a conclusion on the question of the defendant's good faith, and that, if when he filled them he knew they had not been issued by the physican in good faith and in the course of the latter's professional practice only, he nevertheless filled them and gave the drugs called for therein to the parties named, the jury would be warranted in finding the defendant guilty; that if a physician issues a prescription in good faith to cure a patient or to alleviate the suffering of the patient, then the druggist has a right to fill it, but that if a physician issues a prescription not with good intent and not in good faith to effect a cure or to alleviate the suffering of the patient, but for purposes of gratifying the appetite of that patient, then such a paper cannot be called a prescription, and that if a druggist knew the prescription had been issued in that way he would violate the act in filling it

The circuit court of appeals thinks that the theory on which the case was tried and submitted to the jury was untenable, because not within the definition of any of the crimes denounced by the act It does not place on the druggist the burden of inquiry into the intent and purpose of the physician in issuing the prescriptions, to the contrary, it expressly authorizes the druggist to sell on prescriptions issued by registered physicians The law leaves entirely with the physician the responsibility as to when, under what conditions, and for what purposes he will issue a prescription for the drug Responsibility for the issuance of prescriptions is placed on the physician, not the druggist, when brought to the latter to be filled, they are his protection

Nonliability of Head of Roentgen-Ray Department

(Withington v Jennings (Mass), 149 N E R 201)

The Supreme Judicial Court of Massachusetts, in overruling exceptions to a verdict directed for the defendant, says that the plaintiff, by the advice of her family physician, in 1921 went to a hospital which was a charitable institution to have her tonsils removed by the roentgen-ray method At the hospital she was introduced to the technician who was employed by the hospital for roentgen-ray work While administering the third treatment he neglected to use a filter, and as a result the plaintiff suffered an injury for which damages were claimed The defendant was employed by the hospital, he was in charge of the roentgen-ray department, and received for his services one half of the fees paid to the hospital for roentgen-ray work He was not consulted by the plaintiff and she did not see him at any of her visits to the hospital He testified that he specialized in roentgen-ray work, that he prescribed roentgen-ray treatments but did not administer them or take roentgenograms, that this work was done at the hospital by the technician, who was a third-year medical student, employed by the hospital to do this and other work, that he gave the technician directions for the roentgen-ray treatment of tonsils; that the state of the art as "practiced in the community in 1921 called for a standardized dosage without examination by him of the patient", that it was not customary for physicians to administer roentgen-ray treatments or take roentgen-ray pictures; that this work was customarily done by persons having experience in using the roentgen-ray machine, and that he understood that the technician had considerable experience in this work before coming to the hospital

The technician was not employed by the defendant, he was not the defendant's agent or servant They were fellow employees of the hospital The defendant was not responsible for the neglect of the technician in administering the treatment, which was entirely in his control The evidence did not show that any negligent act of the defendant contributed to the plaintiff's damage, he did not participate in the operation, and was not liable for her injury The verdict was directed for the defendant properly The evidence offered by the plaintiff, and excluded by the trial judge, that the defendant's high reputation as a roentgen-ray expert influenced her decision to take the roentgen-ray treatments in his department, was not material and was rightly excluded

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

171: 1-156 (Jan.) 1926

*Endocrine Influence on Metabolism. W. B. Cannon, Boston.—p. 1.
*Effect of Roentgen-Ray Irradiation on Red Blood Cell Production in Cancer and Leukemia. R. Isaacs, Boston.—p. 20.
*Association of Diabetes Insipidus with Osteitis Fibrosa Polycystica. J. D. Heard, F. L. Schumacher and W. B. Gordon, Pittsburgh.—p. 38
Human Cerebrospinal Fluid in System and Diffuse Degenerative Disease Involving Nervous System. C. A. Patten, Philadelphia.—p. 48.
*Electrocardiogram in Myxedema. C. Thacher and P. D. White, Boston. —p. 61.
Megacolon: Résumé of Literature; Case; Ramisection Proposed as Form of Treatment. H. J. Bartle, Philadelphia.—p. 67.
*Treatment of Abscess of Lung. J. A. Miller and A. V. S. Lambert, New York.—p. 81.
*Bacterial Vaccines in Asthma. G. T. Brown, Washington, D. C.—p. 94.
Mechanism of Flow of Bile from Liver Into Intestines. A. Winkelstein and P. W. Aschner, New York.—p. 104.
*Blood Pressure Lowering Principle in Seed of Watermelon (Cucurbita Citrullus). I. S. Barksdale, Charleston, S. C.—p. 111.

Endocrine Influence on Metabolism.—In Cannon's opinion an attempt at present to develop an elaborate and intricate conception of the interrelations of the endocrine glands would be altogether premature and might be quite misleading. The necessary factors are not at hand. But the idea that endocrine factors play an important rôle in establishing and maintaining physiologic equilibriums is reasonable and moderate in its scope, and does not involve a far reaching projection of theory into the unknown.

Effect of Roentgen-Ray Irradiation on Red Blood Cell Production in Cancer and Leukemia.—From the evidence of the effect of irradiation on young red blood cells, Isaacs thinks that all roentgen-ray irradiation may be considered as stimulative. Small doses may stimulate to division, large doses may stimulate maturity and, hence, death from senility, the rate for each tissue varying with its specific growth properties. Cases of cancer and leukemia, in which the increase in granule red corpuscles after irradiation is significant and sustained (two or more days), show a definite clinical improvement, and no leukopenia develops. In those cases in which there is no evident increase in the granule red corpuscles after irradiation, there is usually no clinical improvement in the irradiated lesion. If the increase is temporary (twenty-four hours or less), and is followed by an abrupt decrease, the results are those of too much irradiation, a leukopenia develops, and the patient may become worse clinically.

Association of Diabetes Insipidus with Osteitis Fibrosa Polycystica.—A case is reported by Heard, Schumacher and Gordon, in which occurred the exceedingly rare association of osteitis fibrosa polycystica with diabetes insipidus. The generalized bone disease followed local trauma to the skull. The polydypsia and polyuria did not appear until the osteitis fibrosa was well advanced.

Electrocardiogram in Myxedema.—Fourteen cases of myxedema, studied by Thacher and White, showed consistently a low T wave in lead II before treatment with increase in positive amplitude after treatment. Thus, there is a distinct parallelism between the T wave of the electrocardiogram and the basal metabolic rate in hypothyroidism. In addition, there is a general decrease in potential of all electrocardiographic deflections in all leads in myxedema, with increase after treatment. This same so-called "low potential" in all leads is also found in myocardial exhaustion due to serious coronary sclerosis. This fact is evidence that the heart action is sluggish during myxedema, in accord with the recent finding of Einthoven that the electrical and mechanical expressions of muscular activity are not only synchronous but also tend to be parallel in degree. The T wave in lead II may also be lowered by digitalis; but the "digitalis T" is somewhat different from the "myxedema T" or the "myocardial weakness T," the deflection being more often diphasic, particularly with the S-T interval inverted.

Treatment of Abscess of Lung.—Miller and Lambert aver that the successful treatment of cases of abscess of the lung is materially aided by their joint management by internist and surgeon, with the close cooperation of a skilled bronchoscopist. A systematic plan of prolonged rest, combined with postural drainage, is the basic method of treatment. Into this plan the other methods may be introduced advantageously in properly selected cases. Bronchoscopy is of real value as an aid to drainage in certain cases. Artificial pneumothorax has a very limited field of usefulness. Approximately from 40 to 50 per cent of all cases will eventually need radical surgical treatment. Correct judgment of the indications for operation is the crucial element in successful treatment. In general, it is based on the avoidance of surgical intervention during the acute phases of the disease but without delaying too long and thus allowing the case to drift into the chronic stage

Bacterial Vaccines in Asthma.—One hundred and forty-four cases of asthma have been treated by Brown with bacterial vaccines in accordance with a method described, and of these cases 51 per cent were completely relieved of asthma, 39 per cent were improved in varying degrees, and 10 per cent were unimproved.

Blood Pressure Lowering Principle in Seed of Watermelon.—Barksdale is of the opinion that the active principle of the seed of *Cucurbita citrullus*, to which the name of cucurbocitrin has been given, is evidently a substance belonging to the glucoside-saponin group manifesting certain pharmacologic actions worthy of further study. When both the crude extract and the active principle of the seed were taken orally a number of times, the outstanding effect was a prompt lowering of blood pressure by capillary dilatation, which, in turn, diminishes the peripheral resistance, thereby relieving the laboring heart of a tremendous load. Necropsies on rabbits following lethal doses of the active principle showed congestion and hemorrhages of lungs, liver and kidneys, and marked dilatation of the blood vessels of the bladder wall, with a coincident enormous flow of mucus bathing the cystic mucosa, suggestive of selective action by the drug. With clinical trials in a limited number of cases of moderately increased blood pressure in man, Barksdale obtained a lowering in both systolic and diastolic pressures with a corresponding lowering in the pulse pressure in most of the cases studied. The pulse apparently becomes more stable, and the patients experienced greater comfort; some of them were able to tell when the pressure was rising after the drug had been denied for a few days. In four cases of acute cystitis, the clinical relief was very prompt. In all of the clinical trials, no ill effects were noticed, and for this reason, the drug cannot be considered toxic even in very large doses. It possesses a rather slow and prolonged action. The results in the presence of pronounced arteriosclerosis seem to be very slight. The usefulness of this drug is suggested in cardiorenal conditions, and, perhaps, the other forms, also to the probable specific relief of acute and chronic pathologic conditions of the urinary bladder.

Annals of Clinical Medicine, Baltimore

4: 449-523 (Dec.) 1925

*Essential Thrombocytopenia. W. F. Hamilton and T. R. Waugh, Montreal.—p. 449.

*Diverticula of Esophagus. C. H. Jewett and J. A. Lichty, Clifton Springs, N. Y.—p. 488.
Rational Use of Wassermann Reaction. S. R. Haythorn, Pittsburgh —p. 493.
Wassermann Reaction as Index of Therapeutic Efficiency of Antisyphilitic Drugs. D. L. Belding, Boston.—p. 501.

*Pentosuria; Five Cases in One Family. H. W. Jones and C. W. Nissler, Philadelphia.—p. 505.
Common Sense in Management of Impotence in Male. M. Huhner, New York.—p. 510.

Essential Thrombocytopenia.—The four cases reported by Hamilton and Waugh are said to emphasize one very important practical point, namely, the seriousness of the condition and the need for prompt splenectomy; perhaps not in all cases, because the thrombocytopenic state seems to be in a way a relative affair, but most certainly in cases in which spontaneous hemorrhage occurs. Under such conditions one never knows when bleeding may take place in the brain, and once a diagnosis of essential thrombocytopenia has been made, splenectomy should be performed without delay.

Hypertension; Relation Between Renal Insufficiency and Anemia.—In seventy-six cases of hypertension, the relationship between renal insufficiency and anemia was studied by Adams and Brown. This study seems to show that there is a close parallelism between erythrogenic and renal function in cases of hypertension, similar to that found in glomerulonephritis. In cases of hypertension with arteriosclerosis during periods of renal failure, the hemoglobin and erythrocytes were diminished. The recovery of the blood does not parallel the recovery of renal function. The presence of anemia in cases of primary hypertension and consequent arteriosclerosis, in the absence of complicating disease or gross loss of blood, is regarded as being good evidence of existing or preexisting renal insufficiency.

Diverticula of Esophagus.—In four of the six cases reported by Jewett and Lichty there was present an apparent oversupply of saliva and it is believed that this is of pathognomonic significance. The authors are of the opinion that advancing age may furnish a reasonable cause for most of the diverticula of the esophagus, except for those caused by a previous inflammatory condition in and about the esophagus. The explanation given is that the years and years of swallowing consequent to long life finally produce a separation of muscle bundles; then the mucous membrane, with the submucosa, protrudes through the chink, thus forming a diverticulum. The pouch is most likely to occur at the upper end of the esophagus because the direct pressure brought about by the act of swallowing seems greater in the intrapharyngeal region than elsewhere.

Familial Pentosuria.—Jones and Nissler report five cases occurring in one family, all of the essential type. The initial case was one of cyanide poisoning in which both glucose and pentose were found. The dextrosuria was complicating. The only symptoms that these patients presented were those of an unstable autonomic nervous system. Pentosuria does not become dextrosuria.

Archives of Internal Medicine, Chicago

37: 1-150 (Jan. 15) 1926

*Blood Sugar Curves in Epidemic Encephalitis. J. Kasanin and G. P. Grabfield, Boston.—p. 102.
*Intestinal Chemistry. III. Salivary Digestion in Human Stomach and Intestines. O. Bergeim, Chicago.—p. 110.
*Parallelism in Treatment of Tuberculosis and Cardiac Disease. H. J. Howk, Mount McGregor, N. Y.—p. 118.
*Vital Capacities of One Thousand Surgical Patients. H. J. Moersch, Rochester, Minn.—p. 128.
*Refractometric and Viscosimetric Indexes of Cerebrospinal Fluid. A. Levinson and A. M. Serby, Chicago.—p. 144.

Liver Injury in Thyrotoxicosis.—Tests of liver function have been made by Youmans and Warfield in forty-four patients with thyrotoxicosis. In twenty-eight of the patients tests of the glucose tolerance also were made. Twenty-two, or 50 per cent, of the patients in this series showed an impairment of liver function according to the tests of liver function used. Twenty-one of the twenty-seven cases satisfactorily tested showed a decreased glucose tolerance. No relation was found to exist between the functional efficiency of the liver as tested and the glucose tolerance, basal metabolic rate or other features of the disease, except loss of weight. The impairment of liver function in thyrotoxicosis seems to be associated to some degree with loss of weight.

Blood Alkalinity in Diabetes Mellitus.—Foshay found that in young, untreated diabetic patients there is evidence of some diminution of the blood alkalinity at all times. This rapidly disappears under insulin treatment. In untreated, arteriosclerotic diabetic patients there is no evidence of diminished blood alkalinity unless the patient is nearly in coma. In a case of extreme exsiccation from water deprivation cited, the blood picture was similar to that which occurs in acute diabetic coma. The chief differences are the greater retention of inorganic salts and a lesser glycemia.

Focal Typhoid Infections.—Five cases of typhoid infection in various localizations entirely devoid of the clinical picture of typhus abdominalis, and probably without its characteristic anatomic changes, are reported by Landau and Fejgin. In one case, in the absence of all clinical symptoms of typhoid, there was only the multilocular and characteristic localization of the infection which attacked at the same time the liver, the respiratory tract (broncholitis sinistra inferior) and the kidney. The second case was an infection produced by the Eberth bacillus under the form of an acute hemorrhagic inflammation of the large bowel, and an inflammation of the kidney pelvis, all without any clinical symptoms of typhoid. In the three remaining cases the typhoid infection took the form of an acute illness of the liver and bile ducts, with jaundice, leukocytosis and neutrophilia, although in its further course were observed symptoms of typhoid—diarrhea, swelling of the spleen, etc. On postmortem examination in one of these cases, none of the characteristic changes of typhoid fever were seen, especially no affections of the mucous membrane of the intestine. The authors warn against assuming that the existence of typhoid bacteremia and a positive Widal reaction in high dilution, 1:400, 1:800, along with a high temperature is always an absolute proof of typhoid.

Effect of Heart Muscle Disease on Electrocardiogram.—The outstanding feature of the study reported on by Master and Pardee seems to be the variability of the electrocardiographic abnormality when extensive chronic lesions of the ventricular muscle are present. There was apparently no specific relation between the type of electrocardiographic abnormality and the pathologic process found in the heart.

Acute Rheumatic and Subacute Bacterial Endocarditis.—Eighty cases of subacute bacterial endocarditis that came to necropsy are compared by Clawson and Bell with thirty-five cases of rheumatic endocarditis, eighteen of which came to necropsy. The remaining seventeen are typical cases of rheumatic endocarditis clinically, and *Streptococcus viridans* was isolated from all of them. The authors assert that experimental endocarditis and myocarditis similar to human rheumatic lesions can be produced in rabbits by injecting streptococci. The streptococci, generally the viridans strains, seem to be responsible for both rheumatic and subacute bacterial endocarditis.

Water Metabolism.—Andrews is of the opinion that certain hitherto inexplicable clinical phenomena may be explained on the basis that the water reserve is an active factor in water absorption and excretion.

Glucose Utilization in Renal Glycosuria.—The results of the administration of glucose on the respiratory quotient, total metabolism, blood sugar and glucose excretion in four cases of renal glycosuria are given by Paullin. Apparently, patients with renal glycosuria metabolize and store carbohydrate in the same way as normal persons. So far as the evidence points, they do not develop diabetes mellitus.

Physiology of Synovial Fluid.—The concentration of certain of the chemical constituents of nonpurulent synovial fluid from arthritic patients with joint effusion has been determined by Cajorie et al. Changes in the composition of the blood have been induced experimentally by glucose feeding, administration of sodium bicarbonate and exposure to external heat. The effect of such blood changes on the composition of synovial fluid has been observed. The concentration of the diffusible constituents of synovial fluid uninfluenced by experimental feeding closely approaches that of blood plasma. It has been found that, following glucose ingestion, the sugar concentration of synovial fluid promptly rises to a level as high as, or higher than, that in venous blood. It is concluded from such experiments that diffusible substances pass easily from the blood to the synovial fluid and that the gastrointestinal tract must be regarded as being in surprisingly close communion with the joint fluids. The possibility of detriment from this source is pointed out. The adequacy of the synovial fluid for the nutrition of cartilage from the standpoint of carbohydrate and energy yielding content is clearly indicated. Experiments involving changes in the acid base equilibrium of the blood have not shown corresponding changes in the synovial fluid.

Blood Sugar Curves in Epidemic Encephalitis.—The blood sugar curves performed by Kasanin and Grabfield in seventeen cases diagnosed epidemic encephalitis or its sequelae deviated from the best established norm with such frequency that it may be concluded that there is a fundamental disturbance of the sugar metabolism in this disease. The derangement of the sugar metabolism persists in patients suffering from mental sequelae of this disease.

Salivary Digestion.—Studies of salivary digestion in the stomachs of normal men reported on by Bergeim showed on the average 76 per cent of the starch of mashed potatoes and 59 per cent of the starch of bread to be converted into maltose, an additional percentage being changed to dextrins. This considerable degree of starch conversion was generally brought about within from fifteen to thirty minutes after the meal was finished, active amylase disappearing and free hydrochloric acid appearing simultaneously. To function in the intestine, saliva must escape the action of acid gastric juice.

Treating Cardiac Patients in Tuberculosis Sanatorium.—Howk details the results obtained in the treatment of 440 cardiac patients in a tuberculosis sanatorium. The general plan of treatment provides for complete bed rest of every admitted patient until the essential examinations have been made, the period of rest depending on the condition of the vascular system and the patient's response to treatment. In the sanatorium, the period of bed rest has averaged forty-five days. The patient's physical resources are tested gradually to determine the limits within which he can exercise without danger. This period of graduated exercise is continued persistently until it is demonstrated either that the vascular system has not enough resources to enable the patient to resume work, or until he can take up an occupation.

Vital Capacity of Surgical Patients.—Determinations of the vital capacity of the lungs are not regarded by Moersch as a diagnostic measure in itself, but rather as an aid to diagnosis, just as the use of the thermometer and sphygmomanometer are aids.

Refractometric and Viscosimetric Indexes of Cerebrospinal Fluid.—Sixty-six specimens of cerebrospinal fluid obtained by Levinson and Serby from nonmeningitic and nonsyphilitic patients gave a refractometric reading of from 1.33472 to 1.33545, with an average of 1.33508. There were two exceptions to this rule, namely, one case of hydrocephalus and one case of compression myelitis, both of which gave an unusually high reading. In fluid from active and inactive syphilis, the refractometric reading varied between 1.33513 and 1.33557, with an average of 1.33525. Seven cases of tuberculous meningitis gave refractometric readings varying between 1.33475 and 1.33616, with an average of 1.33530. In fifteen fluids from three cases of meningococcus meningitis, the readings varied between 1.33487 and 1.33644 with an average reading of 1.33544. Eleven fluids from seven cases of other forms of purulent meningitis varied between 1.33497 and 1.33924, with an average reading of 1.33618. The viscosity in sixty-two out of sixty-six fluids from nonmeningitic cases ranged between 1.04 and 1.09, with an average reading of 1.05. The viscosity in seven fluids from cases of tuberculous meningitis varied between 1.05 and 1.18, with an average reading of 1.09. The viscosity in fifteen fluids of meningococcus meningitis varied between 1.07 and 1.14, with an average of 1.11. The viscosity in fluids from other forms of suppurative meningitis also averaged 1.11.

Treatment of Surgical Complications of Diabetes Mellitus. R. C. Cochrane, Boston.—p. 247.

Tragedies of Tooth Extraction.—Blumer cites five cases of infection which followed the extraction or treatment of infected teeth. The different types of fatal lesion which may result from tooth infection are grouped as follows: (1) Direct extension of the local inflammatory process with spreading inflammation, which may even invade the mediastinum, and death from toxemia; (2) metastasis to neighboring tissues, such as occurs in cases of meningitis or thrombosis of the cerebral sinuses following tooth extraction; (3) general septicemia or septicopyemia, which may terminate in (*a*) acute septicemia with or without endocarditis; (*b*) chronic septicemia with degenerative processes in the internal organs, or (*c*) prolonged septicopyemia with the formation of abscesses.

Malaria in New England.—Quinn's investigation show that malaria, which has existed in New England since 1634, is still epidemic in southern New England.

Heliotherapy.—Hawes describes his methods of using sunlight treatment among patients in their own homes scattered in New England. He shows how easily this can be done, providing certain dangers are guarded against. Sunlight treatment is indicated in practically all cases of nonpulmonary, or so-called surgical, tuberculosis. It is not indicated in febrile cases of pulmonary disease or when there is other evidence that the condition is active. Actual sunlight is better than artificial sunlight. If the latter is used by means of a lamp it should be as an adjunct to exposure to actual sunlight. Hawes stresses the fact that heliotherapy should not be regarded as the only means of treatment nor as the most important means of treatment, but as an adjunct to rest, fresh air, proper nourishment and general hygiene. Signs and symptoms of too much sunlight, whether artificial or real, are the same as a tuberculin reaction, probably from the same cause. They are increased temperature and pulse, general malaise, headache, debility, with sometimes renewed activity in the tuberculous focus. Sunlight treatment, whenever possible, should be done under the supervision of the physician in pulmonary cases. This is absolutely essential. Sunlight treatment, in some form or another, can be carried on in the patient's home and does not necessarily require sânatorium or hospital equipment. Sunlight treatment should be carried on methodically and if possible according to a definite schedule.

Icterus Index Test in Anemias.—Murphy regards the icterus index test as a reliable aid in differentiating between primary and secondary types of anemia. Slight and transient jaundice, such as may follow an acute gallstone colic, may be demonstrated in most instances. The course of a jaundiced case may be followed more accurately than is possible by means of simple observation. It may be possible to prevent serious liver upsets in patients under treatment with arsphenamine, if treatment be discontinued following rise in the icterus index.

Organization and Operation of Health Department of Tennessee Coal, Iron and Railroad Company. L. Noland, Fairfield, Ala.—p. 78.

Is Ethyl Gasoline Poisonous?—Experiments done by Flinn indicate apparently that animals exposed to skin application of ethyl gasoline will store lead; also that the rate of excretion does not equal the rate of absorption. It was noticed at various times that if for any reason the animal which may appear sick was not exposed for several days, it will show a marked improvement. Evidently its condition before the rest was due to lead exposure. This may account for the fact that so far no cases of lead poisoning have been found at filling stations or in garages. The time between the man's exposures may be long enough to permit him to remain in apparent good health though he may be storing lead. It may take years before he stores enough or before a sufficient change takes place in his metabolism to cause the symptoms commonly attributed to lead poisoning. The fact to bear in mind is that there is no doubt that a storage of lead takes place under exposure, and that lead stored in the body constitutes a potential lead poisoning.

Nitrobenzenes Are Poisonous.—Observations of cases has led Renshaw and Ashcroft to the conclusion that mononitrochlorobenzene is a poison affecting chiefly the blood, as is also the case with other nitrobenzene compounds. Its effect is cumulative, and when a sufficient quantity has been absorbed, toxic effects may occur which are hastened in some cases by a meal or by alcoholic drinks. Toxic effects may be delayed owing to the gradual action on the hemoglobin of the blood. Thus all these patients collapsed some hours after leaving work. The cyanosis and collapse appeared to progress to a maximum, after which gradual recovery, extending over some weeks, occurred. The dyspnea on exertion seemed to develop in each case a day or two later and to correspond with the period of the lowest red cell count; as the patient's dyspnea and cyanosis disappeared, the blood picture approximated more and more to the normal. In this type of poisoning there is an initial collapse, a typical color, and a delayed anemia with a high color index. There is no jaundice, and no nucleated red cells were seen in any film. Some red cell distortion and a few small forms are the only changes noted. The white cells are not affected.

Prophylaxis in Industrial Lead Poisoning.—To obviate the possibility of lead absorption in lead workers McKail proposes that the mouth, teeth and gums be washed well with a solution containing soluble sulphates, such as magnesium and sodium, and sulphuric acid, the acid being added to activate the solution, and that some of the solution be swallowed. Thus, such soluble lead as may have been swallowed in the saliva and pharyngeal secretions, and even postnasal excretions, will be precipitated in the stomach. It is recommended that the solution should be used at all cessations from work, which would be two or three times a day.

Rôle of Prostate in Focal Infections.—In Walther's opinion the prostate and seminal vesicles play an important rôle in considering focal infections in the male and merit more serious consideration at the hands of the profession than has been accorded them so far.

Negative Pressure in Treatment of Raynaud's Disease.—Crichlow reports good results from the use of negative pressure in the treatment of a case of Raynaud's disease involving the feet. The amount of air exhausted depends to a large extent on the patient's ability to stand pain. After keeping the air exhausted from one to two minutes, it is necessary to release the tube and let the air come back into the jar; then, renewing the process of exhausting the air from the jar and letting it back for an interval of from fifteen to twenty minutes, depending on the ability of the patient to stand the same. This was repeated twice daily for the first week, then once daily for the next two weeks, then twice a week for the next month, and later once every ten days, keeping this up for at least a year. The results were most gratifying. The condition is entirely under control.

Use of Mercurochrome in Septicemia.—Stringer concludes that mercurochrome-220, used intravenously, is not a panacea in septicemia. Its action is most likely that of an agent to produce a systemic reaction, emphasizing the natural defenses of the body. Though its use is not without danger, its low toxicity recommends its use in extreme cases, and affords a not wholly explained chance of benefit in those cases with a certain margin of "fight" still present.

Aseptic Meningitis and Dementia Praecox.—Barr and Barry aver that the introduction of sterile inactivated, normal horse serum, by a series of treatments, into the spinal canal of cases of dementia praecox produces (*a*) a marked physical reaction with high temperature; (*b*) an aseptic meningitis; (*c*) mental improvement of varying degree in a large percentage of cases. Younger patients are more responsive and their improvement is more lasting Certain patients are unsuited: those over 45; those having tuberculosis; those having other systemic diseases, as arteriosclerosis, cardiorenal disease, general adenopathy, persistent thymus, etc. The authors are of the opinion that the reactions observed and mental improvement noted are most probably not due to any specific virtue belonging to horse serum, but so far they have found no other agent or method of treatment which yields the same result.

Cooperation Reduces Surgical Morbidity.—The cooperation of internist and surgeon in the preoperative preparation of patients has strikingly reduced the surgical mortality in various types of diseases In Eusterman's opinion a similar pooling of therapeutic resources after operation should reduce surgical morbidity to a minimum. The patient who has been well chosen and skilfully operated on invariably does well without any exact postoperative regimen. The use of proper diet, alkalis, frequent findings, and so forth, immediately after operation, for about six weeks at least, and for a longer period in certain types of cases, rests on sound experimental and clinical ground The better end results in the medical or surgical treatment of peptic ulcer in women than in men are largely due to their superior personal and eating habits and better cooperation in general. The habitual or excessive use of tobacco is harmful to the patient with peptic ulcer.

Surgery of Stomach and Duodenum.—As the result of more intensive study and preoperative preparation of these patients Balfour says there were only four operative deaths among 400 cases: one from bronchopneumonia ten days after a difficult partial gastrectomy for advanced carcinoma involving the pancreas, the resection having been ill advisedly undertaken as a palliative measure to relieve obstruction; one from acute pancreatitis following partial gastrectomy for multiple gastrojejunal ulcers associated with subacute pancreatitis; one from the extension of a retroperitoneal infection into the general peritoneal cavity ten days after excision of a large bleeding duodenal ulcer of the posterior wall and followed by gastro-enterostomy in a patient with marked secondary anemia; and one following jejunostomy for a large subacute perforating ulcer at the cardia in a patient whose condition was so bad that even this operation was questionably advisable.

Hyperthyroidism in Children.—Dinsmore feels that hyperthyroidism in children is more common than has been supposed. The etiology is unknown. A small percentage of cases follow acute infections, but ordinarily there is no tangible factor to which the disease can be attributed. The onset is abrupt and the clinical course rapid. Induced hyperthyroidism may follow the prophylactic use of iodine in a very small percentage of cases but this can usually be controlled by the discontinuance of the iodine. These children are extremely susceptible to all kinds of operative procedures and must be handled with extreme care. In the presence of other foci of infection, the goiter should be removed first, the other foci of infection being removed after the patient has recovered from the thyroidectomy.

Rehabilitation of Cardiovascular Patient. — Lahey and Hamilton direct attention to the occasionally indicated method with which they have succeeded in rehabilitating patients with cardiovascular disease by indirect surgical measures. This consists in the removal of surgical burdens. The order of the greatest degree of accomplishment is removal of the toxic goiter, removal of large pelvic tumors, and removal of troublesome gallbladders. If there is cooperation between cardiologist, anesthetist and surgeon, not only will the mortality in this seemingly hopeless group be surprisingly low, but the degree of restored ability in many cardiovascular cases will be strikingly high.

Preparation for Prostatectomy.—To undertake cystostomy before the urea content of the blood is below 100 mg. for each hundred cubic centimeters, Bumpus says, is to diminish materially the possibility of the patient's recovery, as so reduced a renal function will frequently not bear the added load imposed by the prostatectomy.

Surgical Preparation in Cases of Urinary Obstruction.—The successful management of these cases, Hunt says, demands drainage of the bladder preliminary to prostatectomy for at least ten days, often for longer periods. This has been accomplished by permanent urethral catheter, followed by the one stage visualized suprapubic prostatectomy in 80 per cent of the cases. The adoption of this principle of management in all cases has resulted in the removal of the prostate gland in 204 cases at the Mayo Clinic with but three deaths, in 172 consecutive cases of which the one stage operation was employed with but one death.

Muscle and Fascia Suture in Herniotomy.—These experiments done by Koontz show that muscle unites with fascia by the union of the fascia with the fibrous components of the muscle, and that the strength of this union depends on intimacy of contact between the fascia and the muscle. It is necessary, therefore, that both muscle and fascia be stripped of areolar tissue before they are sutured together. Still better results are obtained if raw surface of muscle is sutured to fascia.

Necrosis of Corpus Luteum.—Two cases are cited by Brannan and Cohen. They are said to be the only cases on record. In the first case the subject was a primipara who presented the clinical features of pernicious vomiting in the third month of pregnancy. The illness was acute and progressive, terminating in death forty-four days after the onset. Aside from marked pulmonary edema, the postmortem examination, so far as the gross findings were concerned, revealed little of significance. Microscopically, the extensive coagulative necrosis of the corpus luteum constituted by far the most important lesion. In the second case, the clinical picture was also that of pernicious vomiting in early pregnancy. This patient was a multipara in the third month of gestation. The duration of the illness was less than a month. The presence of jaundice and the high nonprotein nitrogen of the blood were unusual features worthy of note. With the exception of edema of the lungs and adenomatous goiter, the necropsy findings were not remarkable. The important lesions microscopically were in the corpus luteum, in the liver and in the decidua. The massive necrosis of the corpus luteum was by far the most marked lesion found.

Corpus Luteum Hormone.—Johnston and Gould are inclined to believe that the corpus luteum does not secrete the hormone which produces hyperplasia of the uterus and vagina.

Treatment of Fibromyoma of Uterus.—Reviewing a large series of cases of fibromyoma of the uterus treated by operation and by radiotherapy Ford says a relatively high percentage of the latter group has been found to require further treatment, either repeated radiation (18 per cent) or operation (13.7 per cent) as compared with 4 per cent of the surgical group who received further treatment. It is true, however, that more recent cases, particularly after roentgen-ray treatment, are showing definitely better results through greater experience in the dosage required. A study of individual cases shows so many thoroughly satisfactory results with radiotherapy that the discrepancy in the total results, Ford says, must apparently be attributed to injudicious selection of cases, or to inadequate dosage. Great care must be exercised to rule out malignant disease at the time of radiation. Curettage should precede treatment in any case with suspicious symptoms.

Blood Calcium in Eclampsia.—A study made by Feinberg and Lash of the blood calcium level in eclamptics has shown that on theoretical grounds a decrease in the blood calcium may be expected in eclampsia, although there is no appreciable relation between the blood calcium and eclampsia.

Cysts of Semilunar Cartilage.—Allison and O'Connor report two cases of cyst of the external semilunar cartilage and one case of cyst of the internal semilunar cartilage. It is their belief that these cysts represent the end-result of a degenerative process caused by an interference with the blood supply of the cartilage in this region, the exciting cause of which is a nonlacerating injury. The cysts were located in the midportion of the semilunar cartilage on the external border. Spontaneous recovery is unknown and recurrences have taken place in those cases in which the entire cartilage was not removed.

Operation for "Dangle Foot."—Morison and Mackenzie fix the ankle by making osseous ligaments between the tibia and fibula above and the astragalus and os calcis below. Bone grafts are taken from the crest of the tibia. Details of procedure are given.

Molding Callus to Correct Hip Joint Deformity.—The method employed by Abbott and Jostes consists in a gradual molding of callus. A subtrochanteric osteotomy of the femur is done and the limb fixed in the position of deformity by applying a Thomas splint with traction. When callus has surrounded the bone ends, gradual correction of the deformity is obtained by changing the position of the limb. For example, in abduction deformity, the leg is gradually adducted until it becomes nearly parallel to its fellow. With each change in position a bending of the callus occurs. When the final position of correction is secured there is produced a definite angulation at the site of osteotomy. Correction of the deformity is obtained, therefore, by creating a malunited fracture of the femur but without any displacement of the fragments. The desired position for function is maintained until consolidation of the callus has taken place.

Traction on Sternum in Rib Fracture.—In the case reported by Jones and Richardson, under procaine anesthesia two incisions, about 1 cm. long, were made just lateral to and at right angles to the border of the sternum at the level of the third interspace, and were carried down until the edges of the sternum were exposed, great care being taken to avoid puncture of the pleura. An ordinary "bullet forceps," such as is used to grasp the cervix in gynecologic cases, was used to grasp the sternum, a hook being placed into the lateral aspect of the sternum on each side and the forceps then being locked. It was found that a moderate degree of traction served to keep the sternum elevated during inspiration. The optimum degree was determined by hand and maintained by the usual method of weights and pulleys, attached to a rainbow frame.

Trigeminal Reflex Phenomenon.—By means of a certain form of stimulation applied to a part of the skin and mucous membrane supplied by the second branch of the trigeminal nerve, a reflex can be elicited which consists in (*a*) arrest of breathing in any phase; (*b*) movement of the floor of the mouth and of the root of the tongue; (*c*) movement of the larynx, and (*d*) increase of pressure in the nasal cavities. This reflex resembles in many respects the swallowing reflex. Palthe says that biologically this reflex may be considered as a protection against the entrance of harmful substances into the larynx and pharynx. It acts also during unconsciousness. The unpleasantness which arises when a strong current of air strikes the face is explained by this phenomenon. This "reflex swallow" may have localizational value in distinguishing between disorders in the trigeminal sensibility of peripheral origin and those due to more centrally situated lesions, above the linking center of these cerebral nerves.

Chickenpox Myelitis.—Krabbe reports a case of myelitis caused by chickenpox and probably produced by the varicella virus itself. The favorable course of the disease agrees with the good prognosis of chickenpox.

Treatment of Traumatic Neuritis of Ulnar Nerve.—In Platt's opinion there is one simple and effective operation which is universally applicable in all cases of traumatic neuritis of the ulnar nerve in the postcondylar groove, viz., anterior displacement of the nerve trunk.

Repair of Cruciate Ligaments.—Edwards uses the tendons of the gracilis and semitendinosus muscles to make new cruciate ligaments. These tendons are passed through a drill hole in the internal femoral condyle and then through drill holes in the head of the tibia. The canals lead from the upper surface of the tibia forward and downward so that when the tendons are passed through them they are sutured on to either side of the tibial attachment of the patellar ligament.

Internal Urethrotomy.—Of 107 patients on whom this operation was performed two died. In the first of these, carcinoma of the bladder, vesical calculus, and purulent nephritis were associated with the urethral stricture. In the second case irregular pyrexia ensued, and one rigor followed the dilation. Death occurred on the twelfth day. At necropsy the bladder was found dilated, hypertrophied and inflamed: the kidneys were hydronephrotic and showed a condition of pyelonephritis. Huddy urges that the operation should be preceded by suprapubic drainage of the bladder if there is evidence of renal insufficiency or marked urinary infection. A periurethral abscess should first be drained, and internal urethrotomy performed when the infection has subsided. Urinary extravasation is best treated by free incision into the infected parts, combined with perineal drainage of the bladder, internal urethrotomy being performed at a subsequent operation. The dangers of hemorrhage have been exaggerated. The results are extremely satisfactory, and the operation should be carried out in any case in which dilation is difficult or unsatisfactory. An indwelling catheter has value, and should, unless any complication arises, remain in position four days. Postoperative dilation is essential.

Epithelial Hyperplasias in Breast.—There appears to Cheatle to be a definite sequence of events in epithelial changes in the breast that end in carcinoma. The different epithelial changes have a common site of origin, namely, the acini and terminal ducts. The chain of events may be interrupted at any point, due either to intrinsic biologic changes in the cells or to extrinsic factors such as variation in connection with the exciting cause. The interruption may result in the process remaining latent or in its subsequent degeneration and disappearance. The sequence of events begins as what Cheatle terms a desquamative epithelial hyperplasia, and passes on to an epithelial hyperplasia which is not desquamative and is termed dysgenetic epithelial hyperplasia. The events described as occurring in the breast are identical in time and sequence with those occurring in the skin of man and mice after the application of tar.

Tumor of Neck.—The remarkable feature of Hallilay's case was the way in which the growth had separated the constituents of the carotid sheath, the right vagus being stretched over the front of the tumor, while the right carotid and jugular were displaced to the left of the middle line.

Infantile Paralysis in Australia and New Zealand.—Gill avers that there have been many epidemics of this disease in New Zealand and Australia. The first occurred in Sydney in 1903, during November and December, when about forty cases were treated at the Children's Hospital. From Sydney it spread during the course of the following year over the greater part of New South Wales and Queensland. From 1903 to 1909 there was an interval, but from 1909 to 1916 there were annual epidemics, always reaching their height in the second half of the summer and in the autumn. There was again an interval till 1921. There were mild epidemics in Sydney in 1921, 1923 and 1924, but none in 1925. In 1923 there were forty cases in the hospital. In 1924 there were forty-five cases in the hospital. The last two epidemics were very similar. They both reached their maximum later than usual. In 1923 most cases were admitted in May, a cool month; in 1924, in March. Both epidemics were mild, with a high recovery and a low mortality rate. A very extensive epidemic visited New Zealand, but not Australia, in 1925.

Action of Pituitary Extract Administered by Alimentary Canal.—Knaus states that when pituitary extract is administered at any part of the alimentary canal—mouth, stomach, small intestine, rectum—pressor action is never observed. When pituitary extract is introduced into the stomach or small intestine, it exerts no influence on uterine muscle. When the extract is administered by the mouth, after a latent period of about eight minutes, it exerts a marked action on the uterus, increasing both the tone and automatic movements. The oxytocic substance is therefore absorbed. The rectum absorbs the oxytocic substance also, although absorption is probably not so complete as with administration by mouth.

Appendicostomy for Relief of Thirst.—Crawford describes a method by which appendicostomy may be performed in a few seconds at the close of any ordinary abdominal operation by means of a stab incision. Before the patient leaves the table, 1 pint of saline and glucose solution is run in through a funnel, and this is repeated hour after hour as long as may be necessary. The chief points about this method are as follows: There is none of the intolerable thirst so common after severe abdominal operations. The pulse slows quickly, and the blood pressure rises. There is very little restlessness. The skin is moist; the mouth and tongue are clear and moist. The kidneys act well. Peristalsis is markedly stimulated. Incidentally, the appendix is eliminated; with regard to the frequent presence of chronic disease in the appendix this is important. The patient is fed without disturbance, whether awake or sleeping. There is no futile coaxing of the rectum to fulfil the functions of the colon, and the stomach is allowed to rest.

Surgery of Pharyngeal Cancer.—There is one method of general utility in the operative treatment of carcinoma of the laryngopharynx, says Trotter. This is the operation of lateral (transthyroid) pharyngotomy, which is the foundation on which all the different procedures, from the simplest to the most elaborate, must be built up. It is primarily a method of access, and depends on the anatomic fact that the laryngopharynx lies within the laryngeal skeleton. If the great cornu of the hyoid bone and the ala of the thyroid cartilage are removed, the wall of this part of the pharynx is disclosed unopened, and through it the situation and extent of a growth can be determined by palpation with some precision. It can now be decided if a radical procedure is possible, and what it should be.

Herniotomy in Infants.—Statistics given by Fullerton are said to prove that operations for hernia in infants and young children are as safely conducted in the outpatient department as in the wards; in fact, from the figures quoted, the balance, if anything, is slightly in favor of the outpatient department. Of 184 children operated on (209 operations), seventy-seven were less than 3 months old and forty-eight were between 3 and 12 months of age. The advantages gained by operating in the outpatient department are: (1) The child, if being nursed by its mother, does not suffer the inconvenience and risk of being weaned. (2) The range of usefulness of the hospital is enormously increased, the beds which would otherwise be occupied by cases of hernia being available for other patients.

Etiology of Intestinal Diverticula.—Three explanations of the occurrence of this condition are given by Davies-Colley: (1) The subperitoneal fat weakens the intestinal wall by inducing a simple atrophy of the muscle from pressure. (2) The fat invades and separates the muscle fibers and so produces weak spots. (3) The fat becomes infected, probably by the intestinal contents, and the muscle in contact with it is weakened by an inflammatory process. This last alternative is believed to be the true explanation of most of the diverticula occurring in the colon, though some in the colon and perhaps most of those in the small intestine, in which infection of the fat is less likely to happen, may be ascribed to one or other of the noninflammatory causes suggested.

*Morbid Anatomy and Histology of Pellagra. W. Susman.—p. 58.
*Use of Massive Doses of Digitalis. A. R. Gilchrist.—p. 65.

Scarlatinal Nephritis.—During the two year period 1921-1922, the percentage of deaths from scarlatinal nephritis in the Edinburgh City Hospital was 6.9; in the period 1923-1924 it was 12. The incidence of the complication also shows a definite increase. It was 1.4 in 1919 and 4.92 in 1924. Joe and Williamson studied nineteen cases. The complication appeared in all cases on the eighteenth day. The state of affairs as revealed by urine examination never stood in any relationship to the severity of the patient's condition. In one case a necropsy was permitted. It disclosed as the chief defect in the kidneys a definite acute degenerative change in the secreting tubules, not, as heretofore stated, in the glomerulus. Fatalities occurred in this series of cases when least expected.

Renal Function in Scarlet Fever.—Percival and Stewart are convinced that no warning of an impending nephritis can be obtained from examination of the blood urea content. They have found an early and a later rise in blood urea to occur. The fall is rapid in those cases which did not develop nephritis, and usually much slower in those which did. In four cases out of six, clinical signs of nephritis—diminished output of urine, albuminuria, hematuria, casts and slight edema, appeared while the blood urea was still low, though in every case there was a subsequent rapid rise.

Morbid Anatomy of Pellagra.—The morbid anatomy and histology of a case of pronounced pellagra was thoroughly examined by Susman. The oldest lesion was in the thyroid, and proliferation of the vesicular epithelium, increased vascularity and intracellular granularity and a marked fibrosis indicate a disease of the thyroid. Metabolic disturbances which followed, and the damage incurred by the causal agent are responsible for the liver damage and consequent fibrosis. This is a slow process. The toxic material is excreted by the kidney tubules, and there causes a peritubular degeneration, and later, fibrosis. The lesions in the other organs are secondary to this, the main process.

Use of Massive Doses of Digitalis.—Gilchrist had employed Eggleston's method of rapid digitalization on over fifty occasions in cases of auricular fibrillation. As a general rule, slowing of ventricular rate occurred within six hours, and maximum effects were reached in from fifteen to twenty-four hours, and often persisted for several days. In cases of fibrillation secondary to rheumatic infection, with the patient acutely ill, with a marked venous congestion and high ventricular rates, the results were often dramatic. In cases of fibrillation secondary to chronic myocardial degeneration and accompanied by advanced arteriosclerotic and renal changes, the method is not always of such value as in the former group, but may be used if the symptoms demand it. In urgent cases the method is less dangerous than the intravenous administration of strophanthin. The response to massive doses is of some value in forming a prognosis. From the practitioner's point of view, Gilchrist says Fraser's method or Pardee's may be employed. It is easy to calculate the dose on the basis of 15 minims of the tincture for each 14 pounds of body weight, and give 20 minims six hourly thereafter until maximum therapeutic effects are obtained. Toxic effects are rare and can be largely avoided by keeping the patient under fairly frequent observation.

Hyperesthesia in Disease of Gallbladder. Z. Cope.—p. 285.

Simple Endemic Goiter.—Simple endemic goiter, in Berry's opinion, is not hypertrophy, but is essentially a degeneration of the thyroid gland. The gland is not overactive, but underactive. Whatever may be the connection between iodine and the thyroid gland, there is no reason for believing that a lack of iodine has anything to do with the causation of endemic goiter, as found in the human subject. It is quite certain that, at least in the vast majority of cases, the disease is produced through the agency of drinking water. There is much evidence that practically all waters which produce goiter contain frequently, although not necessarily at all times and seasons, mineral matter in suspension, usually in an extremely fine state of subdivision. There is also a good deal of evidence that this mineral matter is generally of a calcareous nature. Organic matter in suspension, although capable, apparently, of causing a hyperplasia of the gland, at least in animals, has not been proved the cause of endemic goiter as seen in man.

Fat Soluble Vitamins.—While Drummond cannot give any clear idea, as yet, of the chemical nature of vitamin A, the very highly active fractions he has obtained consist largely of unsaturated higher alcohols, containing in their molecules only the elements carbon, hydrogen and oxygen. The possibility is suggested that the vitamin is actually one of these alcohols. At any rate, one must abandon all ideas of the labile, vitamin being a liable, ill defined compound, as one time imagined, when it is so readily demonstrated that it can survive such drastic chemical treatment as saponification with boiling alkalis and distillation at temperatures over 200 C.

Tubercle Bacilli in Feces.—Two hundred and twenty-five children admitted to Sykes' care either for observation for suspected pulmonary tuberculosis, or with a diagnosis definitely implicating the lung, have had their feces examined for tubercle bacilli as a matter of routine. In addition, and as controls, a number of patients with tuberculous peritonitis, cervical adenitis and children not suffering from tuberculous disease have also been investigated. Evidence is submitted to show that there is little doubt that the acid-fast bacilli found in the feces of children suffering from pulmonary tuberculosis are tubercle bacilli. Further, it would appear that in the majority of cases in which bacilli are thus found, they are derived from sputum which has been swallowed. The possibility of such bacilli being derived from tuberculous ulceration of the intestine has been considered, and though the evidence is small, it is such as to suggest that this is not frequently the source. Tubercle bacilli, if present in the sputum, can be demonstrated in the feces in 100 per cent of cases. In no case in which the sputum on repeated examination was negative for tubercle bacilli were these bacilli found in the feces. In children suffering from pulmonary tuberculosis, tubercle bacilli can frequently be found in the feces when no sputum can be obtained for examination.

Some Medical Aspects of Workers' Compensation Insurance. N. C. K. Lane.—p. 1.
Hydatid Cysts of Lung: Surgical Treatment. W. J. S. McKay.—p. 7.
*Unusual Case of General Paresis. C. Henry.—p. 13.

General Paresis of Long Duration.—Henry reports a case of general paralysis of the insane of over eleven years' duration without remission. The man, aged 35, had had syphilis. Ten months before admission he first noticed the symptoms, which consisted of hearing women's voices coming from the back of his head—which kept him awake at night. He became depressed and apathetic; he thought spirits went inside him and then ran away and laughed and mocked him. He thought that a woman brought him poison in a spoon. His speech was thick and slurred and his tongue was tremulous; there was syllable stumbling and elision of words. Reflexes were normal. Death occurred suddenly while the patient was lying in bed. At the postmortem examination, the cerebrospinal fluid was found much increased in quantity; the brain was very large; there was definite chronic leptomeningitis and on the floor of the fourth ventricle there was hypergliosis. The aorta descendens was the site of an aneurysm the size of the clenched fist. This had ruptured into the right pleural cavity, which contained the whole blood content of the body.

Incidence of Hydatid Disease in New South Wales.—In one district reported on by Ross, about one third of the cattle, sheep and dogs examined were infested with echinococcus. Two hospitals in this district reported that in the last quinquennial period, 1920-1924, the ratio of human infestation was about 1 : 137. In another district, 50 per cent of cattle, 60 per cent of sheep and 10 per cent of dogs were infested. The ratio of human infestation was 1 : 309. Ross says that echinococcus incidence is on the increase in these districts.

Case of Gastrectomy. J. J. Levin.—p. 39.

Tannins as Intestinal Astringents.—The behavior of tannic acid in the intestine is discussed by Gunn and certain clinical observations are quoted. In mild cases of diarrhea, tannic acid would seem unnecessary. In severe cases, especially when the large intestine is affected, it is useless.

Mercurochrome in Treatment of Chronic Septic Endocarditis.—Falconer reports three cases of subacute malignant endocarditis in which mercurochrome-220 soluble was administered. In two of the cases, mercurochrome appeared to produce a definite temporary improvement, as evidenced by a definite effect on the pyrexia, diminution in the size of the spleen, disappearance of the Osler's nodules, and an improvement in general appearance and feelings of the patient; but in neither case did it avert the fatal issue, or materially prolong life. In both cases it produced considerable reaction with severe intestinal irritation and high pyrexia.

*Id. II. Effect of Caffeine on Blood Urea-Nitrogen Concentration. K. Tashiro.—p. 630.

Precipitins of Hemoglobin.—Ishikawa's and Sakurabayashi's investigations are interpreted as showing that the liver and kidney are biologically related; hence, they contain similar antigen.

Effect of Nicotine on Epinephrine Output.—Sugawara's observations show that nicotine, intravenously injected (from 0.025 to 0.5 mg. per kilogram of body weight), called forth, in the first place, a remarkable, but very briefly continued, augmentation of the epinephrin output from the suprarenals of cats. The augmentation began very soon after the injection and continued, as a rule, over about one minute and not longer than two minutes. It was then replaced by the depressant stage, which lasted many minutes. At the time of maximum depression, no epinephrine could be detected in some cases. The epinephrine output of cats whose splanchnic nerves were divided showed also the same tendency against nicotine. Nicotine acts on the suprarenal medulla itself.

Urea Nitrogen Concentration of Blood.—When a normal rabbit is bound, its blood urea-nitrogen concentration increases. After about thirty minutes' fixation, the blood urea-nitrogen content commences to increase during the binding, but in most cases it reaches the maximum in from thirty minutes to an hour after the release, thence making a gradual fall, but not reaching its original value until after two or three hours. A long duration of binding brings about a gradual increase of the blood urea-nitrogen concentration, which is often to be seen doubled after from three to five hours. Tashiro terms this phenomenon "fixation-hypercarbamidemia." This hypercarbamidemia appears lessened in animals previously vagotomized, and if the vagi are cut in the course of binding, the increase of the blood urea-nitrogen concentration is stopped. From these facts it can be concluded that "fixation-hypercarbamidemia" is attributed to the central stimulation of the vagus.

Effect of Caffeine on Blood Urea Nitrogen Concentration.—Tashiro asserts that a small dose of caffeine (0.05 Gm.) increases the blood urea-nitrogen concentration in a rabbit. The increase of the blood urea-nitrogen content caused by caffeine is not only arrested, but rather turns to decrease, by paraldehyde. The blood urea-nitrogen content is not augmented by caffeine in atropinized or vagotomized rabbits; it is rather lessened. Caffeine-hypercarbamidemia is caused by the stimulation of the vagus centers. A large dosage of caffeine gives rise to the decrease of the blood urea-nitrogen concentration.

Experimental Investigation Against Tuberculosis.—Investigations dealing with the influence of oils on *Bacillus tuberculosis* are reported by Tulloch. The most important finding is: that exposure of dry living tubercle bacilli to olive oil having an acid value of 0.75 per cent—reckoned as oleic acid—for four days at 37 C. caused death of the bacilli. At least as much bacillary substance as 1.5 mg. (wet weight) per cubic centimeter of oil could be thus treated with the assurance that the product so obtained was noninfective for guinea-pigs. Experiments with guinea-pigs showed that bacilli so treated possess immunizing properties. Five guinea-pigs having previously been immunized with this oleovaccine were resistant to infection with dried tubercle bacilli.

*Histology of Raynaud's Disease. Grenet and Isaac-Georges.—p. 151.
*Amebiasis. N. Fiessinger and G. Parturier.—p. 153.

Phrenicotomy.—Dufour reports two cases of phrenicotomy. One patient, aged 33, had recurring bronchitis and dilatations of the bronchi, at the base of the right lung. Adhesions contraindicated pneumothorax. The other patient, aged 53, was affected with partial pyopneumothorax just above the right diaphragm. No improvement was noted in either case during the months to date since the operation.

Hemorrhagic Purpura in Myeloid Leukemia.—Chauffard, Clément and Jonesco report a case of hemorrhagic purpura in a patient, aged 51, presenting myeloid leukemia and splenomegaly for two and a half years. The disease had developed in three successive attacks, each having been checked by application of roentgen rays to the spleen. The hemorrhagic purpura, complicating the leukemia, caused death in about three weeks. They emphasize that the pathogenesis of hemorrhagic syndromes in myeloid leukemia is still unknown, but they point to the fact that the patient's spleen had been exposed thirty-three times to the roentgen ray, within two and a half years.

The Turpentine Fixation Abscess.—Comby recalls that the turpentine fixation abscess was first used by Fochier in puerperal septicemia, twenty-five years ago. The treatment became popular and was soon applied in obstetric cases with even slight fever. On account of the extreme painfulness of the fixation abscess, also its uselessness, the method was given up and forgotten. Twenty years later Netter attempted to treat epidemic encephalitis with the fixation abscess. Other physicians used the method not only in acute encephalitis, but also in meningitis, poliomyelitis and postencephalitic parkinsonism. Then came the turn of bronchitis, pneumonia and various infections, influenza, typhus and typhoid. The fixation abscess is being employed for infants as well as for patients of 80. Intolerable pain and fever are not the only inconveniences of the method; sometimes the abscess becomes too large, causing extensive sloughing of the skin, and scarring. In Comby's opinion the barbarous method should be entirely suppressed; he never witnessed any benefit from it.

Histology of the Arterioles in Raynaud's Disease.—Grenet and Isaac-Georges examined the vessels in pieces of skin removed from the affected fingers of three patients with Raynaud's disease. There were lesions testifying to inflammation of the arterioles. This seems to confirm that mere vasoconstrictor spasm cannot induce gangrene, while arteriolitis may be the causative factor of the disease. Two of the patients were syphilitic; in the third the Raynaud's syndrome appeared after a mild infection. These facts may indicate the origin of the vascular changes.

Case of Urinary Amebiasis.—Fiessinger and Parturier observed a case of hemoglobinuria with hemolytic jaundice and splenomegaly in a man, aged 25. The ameba was found in the urine. Evidently the amebiasis was responsible for the hemolytic process; it was probably located in the renal parenchyma. A history of enteritis revealed invasion of the organism by the intestinal tract. All the pathologic phenomena disappeared under emetine treatment.

*Two Cases of Meningoneuritis. J. Ramadier.—p. 193.
Case of Malta Fever. E. Sergent et al.—p. 197.

Fatal Hemorrhagic Conditions in Leukemia.—Emile-Weil knows of a case of chronic lymphatic leukemia complicated by fatal hemorrhagic purpura. He believes that large and repeated doses of roentgen rays may be incriminated for the hemorrhagic condition, inducing an acute attack of leukemia or pernicious anemia. Septic infection, usually occurring with this disease, may also play a certain rôle in genesis of the hemórrhage. Examination of the blood before each exposure will allow suspension of the roentgen-ray treatment at the right time, and thus avert this dangerous complication.

Three Cases of Phrenicotomy.—Moure, Cantonnet and Lebée applied phrenicotomy in two cases of bronchiectasis confined to the base of the lung, and in a case of a tuberculous process in the middle lobe. The improvement was only partial in the two cases with dilation of the bronchi. The third case is recent, and the results are still uncertain. Phrenicotomy should be used cautiously, since the paralysis of the half of the diaphragm may persist permanently.

Meningoneuritis of the Eighth Cranial Pair.—Ramadier describes two cases of complete and bilateral deafness with disappearance of vestibular reactions in subjects with acquired syphilis. Loss of hearing may be the first and sole manifestation of the neurosyphilis. Lesions involving the eighth cranial nerves are associated with a meningeal reaction. Thus the ear affection may be called "syphilitic meningoneuritis." While in one instance the syphilis had not been treated, in the second case the deafness appeared in the course of mercury treatment. Bismuth may be the treatment of choice in these cases.

Anaphylactic Sensitization Persisting for Nineteen Years.—An editorial comments on a case recently published elsewhere. In treatment of grave menorrhagia a young woman was given 10 cc. of horse serum (antitetanus serum) following an injection of ergotin. This induced in less than one minute a very severe anaphylactic shock, only temporarily relieved by epinephrine injections. It did not subside completely until late the next day. Phenomena of serum sickness and urticaria kept the patient in bed for two weeks longer; complete recovery not occurring until after two months. Inquiry revealed that the woman had been treated with diphtheria antitoxin at the age of 2. The interval between the sensitizing injection and the injection unleashing the anaphylaxis was thus nineteen years. This seems to be the longest duration of an anaphylactic condition recorded to date. It is advisable to fraction the antiserum in adults having had a similar injection in childhood. No more than 1 or 2 cc. should be administered at the first injection; waiting a few minutes before injecting the rest.

*Treatment of Retroversion of the Uterus. Luque.—p. 476.

Closed Cyst of the Urachus.—Patel and Labry operated on an abdominal tumor in a woman, aged 37. The tumor, diagnosed as an ovarian cyst, proved to be from cystic dilatation of the urachus. No traces of the vesical and umbilical openings existed, and the cyst appeared entirely closed. About ten similar cases have been recorded to date. The diagnosis was not established until operation or necropsy, since there were no symptoms except those from compression by a tumor. The cyst has no tendency to resorption and spontaneous cure. Intracystic hemorrhage is the most frequent complication; it is associated with abdominal pain suggesting torsion of an ovarian cyst. Peritoneal adhesions are frequent in these cases. Puncture of the cyst is contraindicated, as the fluid reappears very rapidly. Over 70 liters of the intracystic fluid were removed in Hoffmann's case, and 50 liters more were found at necropsy. Extirpation of the cyst, also of the adherent part of the peritoneum, is the proper treatment. No fatalities occurred after the operation; the cure was rapid and permanent.

Treatment of Uterine Retrodisplacement.—With Luque's method for correction of uterine retrodisplacement, he makes a Pfannenstiel incision, takes up a loop in each round ligament, and then draws these loops through the upper part of the aponeurosis, and sutures the loops together. This allows upward extension of the uterus during a pregnancy later. The abdominal route should be preferred since this allows surgical treatment, at the same time, of associated lesions of the adnexa. The curved Pfannenstiel incision is superior to the vertical, while it seems to prevent postsurgical hernia, and leaves an almost invisible scar. This incision is especially indicated in women with fat abdominal walls. The operation is rapid, and the results, he says, are excellent. His experience includes many cases of sterility from uterine retrodisplacement, in which the operation was followed by normal pregnancy and childbirth. He has used this method exclusively in the last four years, calling it the Luque ligamentopexy. He gives seven illustrations of the technic.

The Luxeuil Hot Vaginal Douche. H. Dausset and Gérard.—p. 152.
Sleeping Sickness in Equatorial Africa. M. Leger.—p. 154.

The Psychology of Patients with Biliary Disease.—The nervous disorder accompanying disease of the biliary apparatus may include sleeplessness, also dyspepsia or malaise after the noon meal. About 50 per cent of the patients usually wake up about 2 a. m. and do not fall asleep again till late in the morning. The discomfort after meals consists chiefly in excessive fatigue, somnolency and intellectual exhaustion. The general condition of the patients may remain good, if it is possible for them to sleep in the morning and afternoon, as long as wanted. Otherwise they lose soon in weight, become mentally depressed, incapable of doing any work. The treatment consists in sufficient rest and sleep, full hot baths in the evening (36.5 or 37 C.) for ten or fifteen minutes, the proper diet, and small doses of peptone, from 0.10 to 0.50 Gm., half or an hour before each meal, to aid in desensitization against the evident tendency to protein shock.

*Phrenicotomy in Lung Disease. A. Maurer.—p. 179.
*Asthma and Ultraviolet Rays. P. Duhem.—p. 190.

Phrenicotomy in Pulmonary Disease.—Maurer's experience includes thirty-two cases of phrenicotomy. It was applied for pulmonary tuberculosis in twenty-two; bronchiectasis in six; and gangrene of the lung in four. Phrenicotomy is preferably indicated in unilateral lesions of the lung, confined to the base; in cases with a cavity in the lung, and in the slowly developing form of tuberculosis. The operation may be made when pneumothorax is contraindicated on account of adhesions, and thoracoplasty on account of poor general condition. No operative complications occurred in the thirty-two phrenicotomies. The results in tuberculosis were encouraging; no conclusions can yet be made as to the other cases, since they are recent and few in number.

Ultraviolet Rays in Treatment of Asthma.—Duhem asserts that ultraviolet rays may be useful in asthma in children if only small doses are applied. The first exposure should not surpass two minutes; the next two are prolonged each by two minutes, six minutes being the maximum. The treatment should be dropped if four or five exposures do not induce an improvement; the series may be repeated after a long interval. One child was completely cured, six greatly improved, four less markedly. Recurrence of the paroxysms was noted in two; the results were negative in four. Since exposures restricted to six minutes have been used, there has been no recurrence of the paroxysms under the treatment.

Presse Médicale, Paris

34: 225-240 (Feb. 20) 1926

*Bronchopneumonia in Syphilis. S. I. de Jong and Lestocquoy.—p. 225.
*Metastases in the Prostate in Staphylococcemia. Strominger.—p. 226.
The Filtrable Forms of the Tubercle Bacillus. P. Hauduroy.—p. 227.
*Eliminating Power of the Salivary Glands. L. Binet.—p. 229.

Chronic Bronchopneumonia in Congenital Syphilis. — De Jong and Lestocquoy describe a case of chronic bronchopneumonia in an infant, 9 months old. The disease developed in the form of intermittent fever with extremely severe attacks of dyspnea, paroxysmal cough and progressing cachexia. The clinical picture resembled that of asthma or congenital stridor or compression of the respiratory tract by hypertrophied glands. The skin reaction to tuberculin, negative in the beginning, became positive later. Nevertheless the early appearance of rickets; enlargement of the peripheral glands, hyperleukocytosis of the cerebrospinal fluid and hyperalbuminosis, also a partially positive Calmette-Massol test, suggested the diagnosis of syphilis. At necropsy the lesions of the lungs appeared similar to those in syphilitic white pneumonia. There was sclerosis of the lung, perivascular and peribronchial. The failure of the specific treatment may be explained by its lesser efficacy in congenital compared with acquired syphilis. Besides, it was applied late.

Metastasis in the Prostate in Staphylococcus Infection.—Strominger reports four cases of fatal carbuncle with metastatic abscesses in the prostate. In three patients death occurred from staphylococcus septicemia; the fourth died suddenly from ulceration of a metastatic tumor and subsequent perforation of the coeliac artery. He believes that local immunization induced with Besredka's specific dressings in the beginning of the affection might prevent dissemination of the coccus in the blood stream. Vaccination may thus complete the surgical treatment. In abscesses of the prostate, injections of an autovaccine should be added.

Elimination by Way of the Saliva.—Binet reiterates that glucose may be sometimes found in the saliva while uric acid and urea are always present. Examination of the saliva of thirty-four diabetics revealed the presence of glucose in two. The uric acid content of the saliva is constant, and does not depend on the amount of the saliva. Dosage of urea in the saliva of fifty patients with uremia showed from 330 to 1,140 mg. per liter against the normal 23 to 164 mg. Determination of the urea content of the saliva may give instructive findings when it is difficult to obtain blood for examination in children or adults.

Ether Anesthesia by the Rectum. Robineau.—p. 1847.
Tracheobronchoscopy for the Practitioner. A. Soulas.—p. 1851.
Influence of Operations on Menstruation. H. Vignes.—p. 1854.

Sugar in Preparation for Operations.—Chevrier strives to avert the injurious action of anesthetics on the liver cell, inducing sometimes insufficiency of the organ with consecutive cirrhosis. He thinks this can be accomplished by increasing the amount of glycogen in the liver. For this, large amounts of sweets are given before and after the operation. Fluids in abundance, with jam, fruit preserves, highly sweetened decoctions and milk were ordered the evening before, and a cup of the sweetened decoction again two hours before the operation. Drip proctoclysis with a 4.8 per cent solution of glucose was arranged after the operation. Contrary to the routine opinion, anesthetics seemed to be better tolerated with this method than when given on an empty stomach. The postoperative by-effects were less pronounced but vomiting still occurred occasionally; the cholemia soon disappeared.

Indications for Sodium Citrate in Surgery.—Renaud reiterates that intravenous injections of sodium citrate not only prevent hemorrhage at operations or delivery but are especially effectual in arresting hemorrhages from mucous membranes, such as epistaxis or metrorrhagia. The rise of vascular tension under repeated doses of the drug may be avoided by adding magnesium chloride (sodium citrate 20 parts; magnesium chloride 10 parts; water 100 parts). Usually 25 cc. is injected; sometimes 15 or 20 cc. may answer the purpose. Even 40 cc. seems to be harmless.

*Demography of Cancer. A. Renaud.—p. 132. C'cn.
Erosion of the Cervix. G. Nordmann.—p. 138.

Movable Retroflexion of the Uterus.—Meyer-Wirz believes —contrary to other clinicians—that a movable retroflexion of the uterus may be the cause of various symptoms. No disturbances were observed in 148 of his material of 507 women with retroflexion. He advises to try a pessary. If it relieves the symptoms, the Alexander-Adams operation is indicated.

Demography of Cancer.—Renaud investigated the Swiss mortality statistics from 1901 to 1920. They are especially valuable because of the regularity of medical help and the exact anonymous death certificate system. Switzerland has about 5,000 cancer deaths a year (12.8 per ten thousand inhabitants or 40.9 per ten thousand people over 40 years of age). This means one cancer death every year among 780 inhabitants, or among 220 that are over 40 years of age. Both sexes are about equally affected. The seeming increase since 1901 is chiefly due to the better diagnosis of cancer of internal organs. Increased frequency of cancer of the breast is the only inexplicable exception.

*Streptococcus Toxin in Scarlet Fever. M. Gerbasi.—p. 119.
Cerebrospinal Fluid Test. G. Taccone.—p. 131.
Asthma from Bronchial Nodes. C. Giaume.—p. 150.
Tuberculous Meningitis. F. Morabito.—p. 160.

Agglutinins After Vaccination Against Typhoid.—Auricchio points to the possibility of diagnostic errors in children who had been injected with the usual typhoid vaccine. Their blood contains the specific agglutinin. No agglutinins were observed in children inoculated with Caronia's dissolved vaccine.

Streptococcus Toxin in Scarlet Fever.—Gerbasi found that serums from individuals without a history of scarlet fever may neutralize in varying degree filtrates from streptococci isolated from scarlet fever patients, as well as from other streptococcic diseases, and even the filtrates from cultures of other microbes (typhoid, melitensis, cocci). Injection of filtrates from hemolytic streptococci from sources other than scarlet fever produced in children reactions similar to those with the Dick toxin. He believes that his experiments lower the value of specificity of the scarlet fever streptococcus, but indicate the necessity for further studies.

Serodiagnosis in Tuberculosis. G. Brovelli.—p. 97.
*Serum Shock. M. Cayrel.—p. 101.
The Murphy Button. V. Pauchet.—p. 103.
Case of Leprosy. E. C. Cavalcanti.—p. 114.

Serum Shock.—Cayrel describes grave anaphylactic symptoms in a robust man, occurring five hours after injection of diphtheria antitoxin. The patient had been treated with a total amount of 600 cc. of antidysentery serum a few years before, and had borne without harm a preventive dose of antitetanus serum. Because the first injection did not cure the diphtheria, the antitoxin was administered again, with all the precautions (calcium chloride internally, fractional doses of the serum increasing from 1 to 20 cc.). In spite of this, a new anaphylactic condition nearly killed him.

*Scopolamine and Acid-Alkali Balance. H. Regelsberger.—p. 208.
*Action of Alcohol on the Stomach. K. Leddig.—p. 232.

Species of Streptococci.—Lehmann sees no reason to give up the species specificity of several types of streptococci. The acquisition of a hemolytic property by *Streptococcus viridans,* cultivated on blood agar, may be explained as a character of the viridans, not as proof of unity of streptococci.

Acidity with Different Localizations of Gastric Ulcer.—Loktionowa found that the acidity is usually above normal with ulcers of the pylorus, and below normal with localization in the fundus. She believes that the difference is due to an inhibiting reflex from the ulcer on its surroundings (normally acid secretion in the fundus, alkaline in the pylorus region).

Permeability and Diabetes.—Wiechmann shows again that the blood plasma contains in the majority of diabetes patients more sugar than the erythrocytes, and that injection of insulin is followed by an equal distribution of sugar between these two constituents of the blood. He considers this an indication of the action of insulin on the cell surface, and a confirmation of the theory of diabetes as a disturbance of the permeability of the tissues for sugar. He found also that the concentration of sugar in the plasma from venous blood in diabetes is equal to or higher than in the arterial. This also speaks for a reduced permeability of the capillaries for sugar. The condition is analogous after administration of dextrose. Injection of insulin is followed in diabetes by inversion of the normal proportion of amino-acids in the venous and arterial blood. The latter contains after the injection more than the former.

Scopolamine and Acid-Alkali Balance. — Regelsberger observed an increased alkali reserve and decreased hydrogen ion concentration of the blood after administration of 0.0005 Gm. of scopolamine. With hypersensitive patients (parkinsonism) half the dose was sufficient. The alveolar carbon dioxide pressure was usually lowered, rarely increased. He concludes that the respiratory center is stimulated by the drug. The urine was always alkaline.

Action of Alcohol on the Stomach.—Leddig found a stronger acidity in subacid and hyperacid stomachs after the alcohol test meal than after the Ewald meal. A roll was better digested with alcohol. Admixture of duodenal juice does not change the hydrogen ion concentration much, and it lowers the total acidity only if present in large amount.

Colitis. O. David.—p. 260. C'cn.

Concretion of the Pericardium.—Kirschner and Matthes' patient had the typical signs described by Volhard, namely, weakness of the heart, venous stasis, especially in the liver, ascites, and the typical full veins of the neck and arms even in the erect position and with the arms raised. The jugular veins showed both systolic and diastolic collapse. These symptoms are due to the inhibition of the diastole with obliteration of the pericardial cavity, while a fibrous mediastinopericarditis interferes with the systole. There was only one symptom—dilatation to the right—which differed from the classical picture. The patient improved considerably after pericardiectomy. It revealed lime incrustation which had not been evident in the roentgen plate.

Typhoid Epidemic.—Straub reports on an epidemic of typhoid in Anklam, and on the endemic occurrences of typhoid in Pomerania—including the seashore resorts.

Syphilitic Blood Changes.—F. Klopstock used alcoholic extracts from cultures of *Spirochaeta pallida* and *Spirochaeta dentium* as antigens for serodiagnosis of syphilis. He claims better results than with organ antigens. Injections of killed cultures of spirochetes produced in rabbits antibodies with a better marked specificity toward his extracts than toward heart extracts. He concludes that the serologic changes in syphilis are induced directly by the spirochetes. If the organ lipoids can be used for the test, this is only because the antibodies against the spirochete induce the production of organ lipoid antibodies.

Arsphenamine in Experimental Recurring Fever.—Krantz confirms Buschke and Kroò's observation on the occasional presence of recurrens spirochetes in the brain of mice treated previously with as much as 0.004 Gm. of neo-arsphenamine.

Thoracic Access to Duodenum.—Kohler's patient with a perforation of the duodenum came too late to be operated on in the regular way. In such cases an early, although slight, involvement of the left pleural cavity indicates a retroperitoneal abscess. He opened it through the diaphragm with good success.

Treatment of Fractures of the Spine.—Mülleder recommends the Henle-Albee operation in fracture of the spine—especially of the thoracic or lumbar vertebrae. The implant is useless if nervous symptoms persist after laminectomy.

Tumor of Posterior Mediastinum.—Cokkalis reports successful removal of a large fibroma of the posterior mediastinum.

Volvulus of the Small Intestine. A. Schöttle.—p. 401.
Surgery on Convicts. F. Böhm.—p. 407.

Medical Observations in Paraguay.—Capelle found Paraguay free from gout, rickets and the echinococcus. Ulcer of the stomach and cancer of the gastro-intestinal tract are very rare notwithstanding the prevalence of meat (fresh, without spices) in the food. Cancers of other localizations are common. Wounds heal excellently—probably because of the sunny climate. Tuberculosis is rare, although the race is by no means immune.

Protein Cleavage in Burns.—Eden and Herrmann noted increased refraction and viscosity of the blood serum after burns. The sedimentation speed was increased. The hydrogen ion concentration decreased, together with an increase of the potassium ions. The calcium ions decreased, while the total calcium remained constant. They believe that the alkaline cleavage products containing much diamino-acids decrease the calcium ionization and alkalinize the serum. The subsequent preponderance of potassium causes vagotonia.

Thoracic Duct in Peritonitis.—Klug had no therapeutic results with fistula of the thoracic duct in experimental necrosis of the pancreas nor in peritonitis. Dyes injected intraperitoneally only rarely appeared in the lymph of the duct.

Bone Implants in Tuberculous Spondylitis.—Kipnis implants a bone graft in tuberculosis of vertebrae except with hopeless tuberculosis of other organs, amyloidosis or a fistula. He prefers Henle's technic, using sometimes Kausch's modification.

Sympathectomy in Spontaneous Gangrene.—Stradin had good results in obliterating thrombarteritis. He combines sympathectomy with ligation of veins in spontaneous gangrene and intermittent claudication. He reports an experimental sympathectomy made on himself (a young healthy man). No difference between the two extremities was noted a month after the decortication of the brachial artery. Periarterial injection of alcohol may be used, instead of sympathectomy.

Blood Picture in Appendicitis.—Volk admits expectant treatment in appendicitis, if there are no more than 15 per cent neutrophils with "rod-shaped" (narrow, nonsegmented) nuclei, *no* metamyelocytes, and less than 15,000 leukocytes per cubic millimeter.

Intracellular Liver Ferments.—Staemmler found in vitro that phosphorus inhibits the oxydase and diastase strongly and the liver lipase weakly. When he poisoned mice with phosphorus, the diastase of their liver was only slightly inhibited, while the oxydase action was enhanced and that of the lipase was unchanged.

Peripheral Leukocyte Counts.—Müller and Petersen present evidence of a permanent coupling of the peripheral and splanchnic innervation. They obtained many indications of it in experiments made partly independently, partly in collaboration. The grave hyperinsulinemia from administration of 400 units of insulin to a dog induces a peripheral leukocytosis of sometimes more than 40,000 cells per cubic millimeter. Intravenous injection of 20 cc. of a 20 per cent solution of peptone in this condition reduces it to 1,000 in a few seconds, while it increases the leukocyte content of the internal organs. Waves of this kind can be easily reproduced several times. The permeability of the intestinal capillaries changes parallel with these changes (decrease in internal vasocontriction and the subsequent internal leukopenia or vice versa). Any reaction in either the peripheral or the splanchnic region leads to the opposite reaction in the other. The mature neutrophilic leukocytes always accumulate in the region with parasympathetic predominance and decrease with the sympathetic innervation. The blood counts are the finest indicators of the continuous oscillations in the balance between the periphery and the internal organs.

Test Glycemia with Gastric Ulcer.—Scharpff had found that ingestion of 80 Gm. of levulose in 300 Gm. of water is followed in vasoneurotic patients by an increase of the sugar content of the blood. The ratio to the original level is between 1.3 and 2. In normal individuals the index is 1-1.3. He observed a high index in fifteen patients with ulcers of the stomach or duodenum. He believes that levulose is preferable to the dextrose used by Hijmans van den Bergh und Siegenbeek van Heukelom.

Glycogen Storage and Insulin.—Adlersberg and Porges observed an increase in tolerance in diabetic patients treated with insulin while on a diet rich in carbohydrates. They consider storage of glycogen in the liver as the aim of insulin treatment.

Treatment of Multiple Sclerosis.—Sauer injected small doses (0.05-0.15 Gm.) of silver arsphenamine or 0.15-0.45 Gm. of neo-arsphenamine twice a week in multiple sclerosis patients. The total amount of the former was 3 Gm.; of the latter 2.8 Gm. A 10 per cent solution of calcium chloride was used sometimes as vehicle. He had better results in these patients than in those treated with physical measures.

Blood Phenol in Kidney Insufficiency.—Becher and Litzner found free phenols in the blood not only in the last stage of uremia, as Becher formerly assumed, but also in lighter stages of insufficiency of the kidneys. They may even disappear from the blood temporarily.

Buffered Water for Romanowsky Stain.—Bálint recommends as optimal a phosphate buffer of a $p_H = 6.8\text{-}7.0$ for dilution of the stain and washing of the slide.

Austrian Decree on Proprietary Preparations.—Heubner extols the new Austrian regulations in regard to proprietary preparations. He admires the courage and energy expressed by the decree in its intention to "clean the Augean stables." He points out that the decree follows the rules of the Council on Pharmacy and Chemistry of the American Medical Association as well as the principles which were embodied in the resolutions of the commission on drugs of the German Congress of Internal Medicine, of which he has been a leading member.

Blood Proteins in Diseases.—Leendertz compares the amount of the protein precipitated by diluting the serum with nine volumes of a 0.025 per cent solution of acetic acid with the total proteins. The ratio indicates the relative increase in the most labile protein of the serum.

Intestinal Regulation of Acidity.—Löffler found with Schaudt and Helzer compensatory changes of the hydrogen ion concentration of the feces after intravenous and oral administration of alkaline or acid substances. The reaction of the feces changes within one or two hours after ingestion, before the substance can diffuse directly to the end of the column of feces.

Albuminuria of the New-Born.—Faerber's observations and experiments explain albuminuria occurring in the first few days of life as a sequel of dehydration. Daily administration of any fluid (9 or 10 per cent of the body weight) prevents or cures the condition.

Contagiousness of Measles.—Redlich publishes evidence which sustains the opinion that measles is not contagious later than twenty-four hours after the appearance of the eruption.

Biologic Action of Rays.—Cramer stained the mesentery of living frogs and rats with trypan blue or crystal violet. The color disappeared more rapidly in the living tissue under the influence of roentgen rays and radium. The tint persisted in the dead tissues, and in frogs injected in the winter months. He agrees with Ellinger and Landsberger's explanation of the process as a catalysis of the oxidation.

Resorption and Insulin.—Koref and Mautner had observed that the gastro-intestinal tract of rats fed with 5 cc. of water, milk or even of an 8 per cent solution of magnesium sulphate, and injected with insulin, was empty within an hour. Alcohol acts more rapidly in insulin animals. Curare, which normally is inactive when administered by the mouth, kills the insulin animal. They conclude that insulin accelerates remarkably the resorption from the gastro-intestinal tract.

Lymphogranulomatosis in Child.—Gysi reports a case of lymphogranulomatosis in a neuropathic boy, 11 years old. He had 32,000 leukocytes per cubic millimeter. Of these, 58.5 per cent were eosinophilic polymorphonuclears; 9 per cent eosinophilic myelocytes; 3.5 per cent neutrophils; 7.5 mast cells, and 1 per cent monocytes. The clinical symptoms had begun with a skin eruption.

Physicians for Adolescents. Rüdel.—p. 233.

Comparative Anatomy of Encephalitis.—Joest points to encephalitis in animals, especially in horses, dogs and sheep, and to hydrophobia. It seems that they have an etiologic kinship with the human encephalitis. In all of them inclusions have been found in the ganglion cells.

Fat in Nervous System.—Berberich concludes that the development of myeline nerve sheaths occurs in the medulla and probably in the whole nervous system without any aid by cells containing fat. The latter have a pathologic significance.

Surface Tension of Serum.—Contrary to other workers, Beckmann found considerable variations of surface tension of serum after meals and in different forms of edema.

Diabetic Coma.—Lorant points to the published cases of diabetic coma without ketonuria, and adds another in a young diabetic patient. He concludes that this refutes both the acidosis theory and the theory of a specific toxic action of beta-oxybutyric acid. He thinks that a disturbance localized somewhere in the cleavage of carbohydrates is the cause of coma. Where the muscles are intact (young diabetics), insulin helps. In the elderly, with changes in the heart ("sthenic type"), the prognosis is grave. Premonitory edema of the ankles had been observed in all the cases in which insulin did not help.

Phases of Hormone Action.—Kogan, Kamenew and Mantz used the salivary secretion in their studies on the interrelation of injections of insulin, epinephrine, potassium and calcium. They found that the interval between the injections and their sequence is more important than the dosage. These phases of action depend not on one factor but on the totality of the conditions under which the hormones act.

Peripheral Metabolic Disturbances.—Frey injects 1 cc. of a 1 per cent solution of fluorescein sodium subcutaneously, and takes at intervals of one minute the blood from the proximal vein. The dye appeared in the blood one or two minutes later on the leg with ulcers than on the arm.

Degkwitz' Measles Serum.—Kaupe used Degkwitz' serum on three children who had never had measles and on fifteen with probable, but not certain, history of measles. He injected it, as Degkwitz advised, on the fifth day after the appearance of the rash in the child who was the source of the infection. The three susceptible children developed typical measles. Four of the fifteen others had serum sickness. He advises against the use of this serum in prevention of measles.

Latent Syphilis and Divorce.—Heller discusses a recent decision of the German supreme court. It declared that syphilis which in all probability had been cured before the marriage was not sufficient grounds for divorce. A former decision of the same court, while confirming the divorce in a similar case, took the same attitude toward a man who had been declared cured by a physician as toward a man who did not know that he had syphilis.

Hydronephrosis and Contracted Kidney. Z. Kairis.—p. 138.
*Tenderness of Testis from Injury of Kidney. J. Severin.—p. 149.

Chronic Character of Peptic Ulcer.—Walko found no parallel changes between the subjective disturbances and remissions and the secretory, motor or roentgen symptoms of gastric and duodenal ulcers. He believes that the periods of pains and subjective latency are due only to changes of sensitization of the vegetative nerves of the organ.

Thyroidectomy.—Breitner, Nobel and Rosenblüth determined the basal metabolism in thirty-two adolescents and young adults who had had an operation on the thyroid from one to three years previously. They conclude that with a correct surgical technic there is no danger of hypothyroidism.

The Soft Palate.—Neuda describes changes in the soft palate in various diseases of the gastro-intestinal apparatus. They are more distinct and diagnostically more valuable in young adults than in the elderly. He observed a redness of the soft palate in the majority of patients with ulcers of the duodenum. This corresponds to G. A. Friedmann's finding of polycythemia in many such patients. Ulcers of the stomach or jejunum or appendicitis present no such changes. A yellow color (near the raphe and border of the hard palate) is characteristic of disease of the liver, especially of parenchymatous changes in cholelithiasis and syphilis. In the latter, the blood vessels are frequently indistinct because of a fatty infiltration. A bronzed and yellow discoloration aided him once in the correct diagnosis of pancreatitis complicating gallstone disease. It occurs even in acute cases. He believes that the soft palate represents the beginning of the entodermal layer, and therefore is subject to similar changes as the rest of the gastro-intestinal tract.

The Goiter Question.—Schmitz-Moormann examined the thyroids in the goiter zone of Baden. The percentage of iodine increases slowly from birth to old age (up to 1 mg. per gram of dry substance) and is lower than in regions where the iodine content of the soil is normal. The total content is the same as in normal thyroids. It seems that the enlargement of the gland serves to increase the absorbing surface for the iodine. The growth of a diffuse colloid goiter stops when the iodine content is increased by medication to about 1.7 per gram of dry substance. Parenchymatous goiters contain more water than colloid goiters.

Tenderness of the Testis from Injury of the Kidney Region.—Severin observed in war injuries of the kidney region the same extreme tenderness of the homolateral testis as in kidney colics. The scrotum is not hypersensitive.

Serum Prophylaxis of Measles.—Degkwitz infected monkeys and sheep repeatedly with filtrates from the nasopharyngeal secretion of measles patients or with tissue cultures inoculated with the virus. He made no attempts to isolate the germ. The virulence of the aerobic cultures was so irregular that they were useless for vaccination in man. The serum obtained from the animals treated with them protected to a certain extent children exposed to measles. It failed completely when given on the first or second day of incubation. The best results (protection of 122 out of 134 children) were obtained when the injection was given between the seventh and eleventh day.

Experiences with Measles Antiserum.—Weise used Degkwitz' protective sheep serum in a sanatorium for tuberculous children. He believes that early administration is the most important point, but he obtained a mitigation of the measles even when injecting the serum up to the seventh and ninth day of incubation.

Syphilis Infection from the Cadaver.—Hoffmann points out that the spirochetes may live and multiply in the organs after death. Their movements—even in brains from paresis cases—persisted sometimes for days. Infection of a rabbit with 3 day old necropsy material proved successful. Syphilitic infection acquired at necropsy is not only possible but has been proven beyond doubt in seven cases, and is probable in seven other cases. He queries why such cases are so rarely reported. One reason may be the tendency of the infected physician to keep it secret.

Alimentary Glycemia and Water Metabolism.—Klein and Lang observed in patients with liver disease a steeper and sometimes higher glycemia curve and faster decrease when dissolving the sugar in 1,500 cc. of water instead of 250 cc. Some of the patients had glycosuria with the former technic.

Breathing Type and the Body.—Hörnicke favors the abdominal type of breathing for women. The rarity of chlorosis and of fainting spells at parties may be due to the rarity of tight lacing. Yet even a belt may cause trouble. He observed a higher blood pressure and more rapid respiration and pulse in healthy girls after work with a belt which did not cause discomfort at rest.

The Furnishing and Prescribing of Drugs.—Meinecke, who is president of the Prussian chamber of pharmacists, points to the higher expenses connected with proprietary preparations. He saw once the financial statement of an establishment concerning such a remedy: costs of manufacture, 300,000 marks; propaganda, 1,500,000 marks; profit, 200,000 marks. No wonder that a widely advertised "remedy for rheumatism," consisting of acetyl-salicylic acid and a trace of quinine—selling for 2 marks—represents really only a tenth of this value. The balance, 1.8 marks, is paid for the advertising and middleman. The patient who felt better, after taking a prescribed proprietary preparation, buys it the next time without consulting the physician, and so do his friends. Such prescriptions are convenient, but they injure the physician.

Venous Pressure in the Legs.—Schott found about the same pressure in the veins of the foot as in the ulnar vein, taking the level of the auricle as the base. In standing, the hydrostatic pressure of the column of blood, beginning at the heart, is added to the dynamic pressure in the veins.

Treatment of Emphysema.—Encouraged by Reich's success in treatment of emphysema by a pneumoperitoneum, Ganter, reports on five emphysema patients treated with partial pneumothorax. It diminished the residual air and the patients felt decidedly better. After completion of his work, he learned that partial pneumothorax is being used in emphysema of horses. Schwenkenbecher attempted it once in a man but desisted, because the patient complained of severe pains.

Photochemical Serum Test.—Bültemann made Lange and Heuer's photochemical silver nitrate test with the serum from eighty-seven patients with gynecologic cancers, and controls. All the cancer serums gave a positive result. The reaction was also positive with septic diseases and in lactation; negative in pregnancy.

Prohibition in America and Tuberculosis.—Donath publishes American statistics on tuberculosis mortality. The notable decline which has continued ever since 1920 can be attributed only to the improvement of conditions in respect to hygiene. He concludes from this that the improvement is due to prohibition. He emphasizes that the hygienic, economic and moral beneficial results of prohibition are most evident in New York, Chicago and San Francisco.

Prohibition in Russia.—Dworetsky—after declaring that no communist would say that communism exists in Russia—points out that it may produce a peculiar impression to see that the soviet government, consisting, as he says, of idealists, has reintroduced hard liquors. Yet the situation was such that there was no other way. The prohibition of alcohol, which had been decreed by the czar, was effective at first, but the moonshine production of abominable stuff began soon. Poisonings, blindness, deaths followed. Cologne, denatured alcohol, furniture polish, were consumed in large amounts. At the time of the revolution the distillation was better, and in every peasant's home, as well as in the cities, stills were at work. Even the famine did not diminish the industry, since the peasant preferred hunger to the abandoning of the lucrative trade. The soviet government tried to stop the alcoholism and the wastage of vitally important grain by military measures. The only result was installation of better stills after the old ones were confiscated. The government then started to sell wines; later, beer. The moonshining flourished as before. Then the government tried to sell weak liquor. The Russians did not drink it. At last the government decided to put out the pre-war quality at a high price. It seems that this will end the moonshining and check the criminal element thriving in the trade. The government designated the health commissioner, Semaschko, to start an educational campaign against alcoholism, since the legislative and military measures failed completely.

"Uricoxydase of the Blood."—Flatow corrects his paper summarized in these columns, Feb. 27, 1926, p. 658. He has lately found it impossible to oxidize added uric acid. The oxidizable substance is precipitated by silver lactate, but does not redissolve in tenth-normal hydrochloric acid.

Intracranial Aneurysms. H. Odqvist.—p. 286.

Progressive Amyotrophia.—Wohlfahrt encountered five cases, resembling the Charcot-Marie type, in one family, as he describes. There were records of the same disease in two preceding generations—a total of ten cases in four generations, with eleven members escaping. Transmission was by both sexes, but a healthy member had healthy offspring. The patients said that their condition seemed to improve under moderate exercise and grew worse with repose. He reviews the various theories as to the etiology. In all, the knee-jerk was normal and there were no sensory disturbances.

Stain Test of Kidney Function.—Lundsgaard and Møller regard elimination in two hours of 70 per cent of the phenolsulphonphthalein injected by the vein as the lowest limit of the normal range. A liter of water should be ingested simultaneously with the injection of the dye. Decreased elimination of the dye is an early and delicate sign of incipient insufficiency of the circulation, either general or localized in the kidney. The interpretation of the findings is not dependable, however, if the output of urine is scanty or there is hypertension or other circulatory disturbance. The stain does not pass into edema fluids, ascitic, subcutaneous or pleural. In sixty-seven patients the excretion was protracted in circulatory diseases; the delay was most pronounced in cases with stasis in the liver. The same excretion curve was found in various forms of liver disease, with or without a failing heart. This and other findings suggest that the liver has much to do with the fate of the dye in the body. The elimination curve may throw light on anatomic and functional conditions in the liver, and thus prove a useful diagnostic guide.

*Influence of Chemical Light Baths on Bactericidal Processes in Blood and Serum. V. Genner.—p. 1145. C'cn, p. 1161.

Influence of Chemical Light Rays on Bactericidal Processes in the Blood and Serum.—Genner used the Finsen lamp or the quartz mercury vapor lamp to study the effect of radiation on the bactericidal power of the blood and serum. He was unable to detect any increase at all in human blood serum, and in rabbit serum only occasionally and so slight and transient that other causes may perhaps be responsible for it. Repeated irradiation showed increased bactericidal power in rabbits but he thinks the venesection accounts for this.

68: 1177-1196 (Dec. 31) 1925

*Calcium Content of the Serum. W. T. Andersen.—p. 1177.

The Calcium Content of the Serum.—Andersen found an average of 10.7 mg. of calcium per hundred cubic centimeters of blood serum in persons under 45 and 10.4 mg. above this age in his research on thirty-eight normal subjects or with normal blood findings. The range was from 10 to 11.5 mg., and the findings did not vary on repeated examination of the same subject, except during menstruation when the serum calcium was always increased by about 1 mg. The research was done at the Finsen Light Institute and the influence of the arc light in modifying the calcium content was sometimes unmistakable. With insufficiency of the kidney, the serum calcium was often low but not constantly; in one case this gave the clue to pathologic conditions in the kidneys although the function tests had elicited only normal responses. With hypertension without kidney symptoms, the serum calcium was normal or slightly above. It was below normal in the asthma cases and also with exophthalmic goiter, but in the latter group the preceding roentgen irradiation may have contributed to the low calcium figure. It was low also in two cases of cancer, normal in two others, and exceptionally high (21.8 mg.) in a case of metastatic cancer in the bones.

*Treatment of Tuberculosis with Metal Salts. N. Lunde.—p. 1.
Types of Meningococci. M. Kristensen and O. Moltke.—p. 10.

Treatment of Pulmonary Tuberculosis with Metal Salts.—Lunde refers to Walbum's method which he has applied in fifty-eight cases. The aim is to supply certain salts which are normally present, and which it is assumed are lacking in the tuberculous. He remarks that every sanatorium has had cases in which it seemed to require only a little stimulus to restore the normal balance and start the healing of the tuberculous process, and this treatment is a tentative groping after a stimulus of this kind. Manganese chloride, gold chloride, or beryllium chloride and calcium were the metals used in turn or separately, and the doses were minimal. No untoward by-effects were observed, and the general verdict is favorable.

Dangers of Syringe Used to Induce Abortion.—Fog comments on the increasing number of cases of septic abortion in the hospitals in recent years, the diminishing birth rate, and the increasing number of medicolegal cases of abortion. He gives the details of nine cases of criminal proceedings on account of intra-uterine injections, and describes in detail the findings in eight cadavers in which death had occurred from measures to induce abortion, mostly the use of an ebonite "mother's syringe." As a rule, necropsy failed to reveal any direct injury responsible for the sudden death in these cases. The interval was short between the introduction of the syringe and the fatal collapse; only in one was it as long as five and a half hours. Embolism of the lung or pulmonary artery was not found in any of the cadavers. Fatal shock has been known from such interventions, but Fog thinks that air embolism was probably responsible for the fatality in these cases. It was beyond question in three of those examined with a view to this possibility, and as the findings in all the eight closely corresponded, it is more than probable that air embolism was the cause in all. Although three days had elapsed in one case, the heart still contained large amounts of air. The syringes commonly used for abortive purposes are liable to introduce considerable air with the fluid and induce high pressure.

LYMPHOBLASTOMA (MALIGNANT LYMPHOMA)

AGE AND SEX INCIDENCE, DURATION OF DISEASE, AND THE EFFECT OF ROENTGEN-RAY AND RADIUM IRRADIATION AND SURGERY [*]

GEORGE R. MINOT, M.D.
AND
RAPHAEL ISAACS, M.D.
BOSTON

One of the big problems of modern medicine is to unravel the nature of the group of conditions that have progressive enlargement of the lymphoid tissue as their most prominent feature. Classification leads to clarification, and yet confusion arises from sharp distinctions between conditions that have many resemblances; which may be because some of the conditions are but different phases of the same disease. This is the state of affairs for those disorders with unknown etiology that may be placed under the general heading of lymphoblastoma, a name considered by some as synonymous with malignant lymphoma.

These terms may include lymphatic leukemia (lymphocytic and lymphoblastic), aleukemic lymphatic leukemia (pseudoleukemia, aleukemic lymphadenosis), lymphocytoma, Hodgkin's disease (lymphogranuloma), lymphadenoma, lymphomatosis, lymphosarcoma, round cell sarcoma, leukosarcoma and lymphadenosarcoma. Such conditions as Banti's disease, chloroma and Mikulicz's disease also may be included.

The views and opinions concerning the nature and relationships of such cases are multiple, and thus students of the problem have utilized a constantly confusing terminology, and not infrequently disagree on the exact diagnosis of a given case. Some apply a term that is synonymous with one used by another, while at other times a special type of case is designated by a name used by others to cover a much broader group. Hodgkin's disease with the pathologic histology described by Dorothy Reed is sharply distinguished by many authorities from two other conditions that they term pseudoleukemia and lymphosarcoma. Others inappropriately include as Hodgkin's disease all, more often some, cases of the latter two conditions, and the terms malignant lymphoma and lymphadenoma have been used for such a group alone. Some contend that two types of lymphoblastoma may occur in one patient. Confusion in the group called lymphosarcoma arises because of differences of opinion as to what constitutes this condition and the lack of appreciation of the difference between the origin of tumors involving structures composed of much lymphatic tissue. Pseudoleukemia and aleukemic lymphocytic or lymphoblastic or lymphatic leukemia are essentially synonymous, as is at times the term aleukemic lymphadenosis. Chronic lymphatic leukemia with a leukemic blood picture is the form of lymphoblastoma most easily separated from others. However, except for the peripheral blood picture, no important distinction, even by pathologic examination of tissue, can be made from cases termed pseudoleukemia or aleukemia, and the same case at different times may be given correctly the one name or the other.

It is highly desirable to have uniform terminology and to distinguish the differences of cases falling into this large group here termed lymphoblastoma. The differences are not for special consideration here, but it is wise to recognize four types dependent on their age incidence, clinical features, blood pictures, and pathologic histology of the diseased tissue. Lymphatic leukemia and pseudo or aleukemic, lymphatic leukemia may be considered two forms, and the progressively scirrhous type, usually known as Hodgkin's disease and often regarded as an infectious process, is a third. The fourth type of lymphoblastoma has a distinct tendency to invasion of tissue, to involve the tonsils, gastro-intestinal tract and serous membranes, and shows a multiplication of reticular tissue and lymphoid cells, and is known as lymphosarcoma. To be sure, some cases of lymphoblastoma now considered very different may later be shown to have the same etiology, while others apparently the same may eventually be proved to have different origins.

MATERIAL AND NATURE OF THE STUDY

Knowledge concerning the general trends of disease as related to age, sex and duration, with and without treatment, aids prognosis and the understanding of pathologic states. It is our purpose in this communication to set forth data of these aspects of 477 cases of lymphoblastoma without making special subdivisions, but there are excluded those with a leukemic blood picture for any significant period of time; in other words, cases of typical chronic lymphatic leukemia. Cases of acute leukemia are also not included. The attempt is made to survey broadly facts concerning lymphoblastoma, yet recognizing the desirability to do so in a more detailed manner. Information of the type presented already has been given for chronic lymphatic leukemia.[1]

The statistical study of Desjardins and Ford [2] of 128 cases of "Hodgkin's disease and lymphosarcoma" and that of Schreiner and Mattick,[3] based on forty-six cases of "lymphogranuloma (Hodgkin's disease)," are the chief recent ones comparable to that presented here. The information presented by Bunting[4] concerning age and sex incidence is important. It is recognized that there are other papers bearing on the topics to be discussed, but for the most part they refer to few cases or treat the subjects in a somewhat different manner from that which follows.

---

[*] Because of its length this article is published in two parts, the second of which will appear next week.

[*] From the Medical Services of the Collis P. Huntington Memorial Hospital of Harvard University and the Massachusetts General Hospital.

[1] Minot, G. R., and Isaacs, Raphael: Lymphatic Leukemia: Age Incidence, Duration and Benefit Derived from Irradiation, Boston M. & S. J. **191**: 1 (July 3) 1924.

[2] Desjardins, A. U., and Ford, F. A.: Hodgkin's Disease and Lymphosarcoma, J. A. M. A. **81**: 925 (Sept. 15) 1923.

The diagnosis of some form of lymphoblastoma was established by the pathologic examination of tissue[5] in 85 per cent of all the 477 cases. The clinical aspects of the other 15 per cent were so typical of lymphoblastoma that the cases have been included in the group. These 477 patients came either to the Massachusetts General Hospital (232 cases) between 1901 and 1925, or to the Collis P. Huntington Memorial Hospital of Harvard University (225 cases) between 1913 and September, 1925, or were seen in private practice (twenty cases) since 1916. Forty-eight per cent were seen first since the year 1919, and 19 per cent first came to one of the clinics before 1915. Of the 477 patients, 401 are known to be dead, and seventy-six are living. In some manner about 100 other cases have been studied, but as the observations are incomplete they are not utilized for this report.

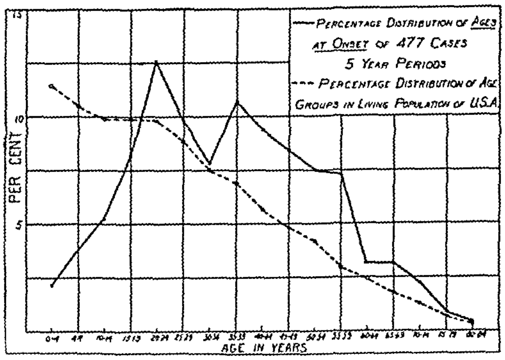

Chart 1.—Solid line, percentage distribution by five year periods of 477 cases of lymphoblastoma arranged according to age at onset; for comparison, a curve (broken line) is shown of the percentage distribution of persons of similar ages in the living population of the United States.

AGE AND SEX INCIDENCE

Lymphoblastoma occurs in both sexes at all ages, but with a varying frequency as to age and sex incidence. The percentage distribution of the age at onset[6] in five-year periods is shown for all the 477 cases in chart 1. A line in this chart shows the percentage distribution of the population in the United States. The general decline in the population after the age of 24 roughly parallels the progressive decrease in the incidence of lymphoblastoma. Two similar curves plotted for ten-year periods show a closer parallelism than those in chart 1 for five-year periods, but the former arrangement of data does not permit the demonstration that lymphoblastoma is relatively rare at the ages of 30 to 34 inclusive.

It has been well recognized that lymphoblastoma occurs with greater frequency in males than in females. In this series there were 327 males and 150 females, or 68 per cent of the former and 32 per cent of the latter, a ratio of 2.12 to 1. This ratio varies significantly for different age groups, as may be seen by inspecting chart 2. There are, however, fewer females than males at all ages except 10 to 14 inclusive. The actual age incidence per hundred males and per hundred females is shown in chart 3, and the absolute number of cases is recorded in table 1. These figures demonstrate that the highest incidence of lymphoblastoma is in patients aged from 20 to 24, with a secondary rise in frequency in those from 35 to 39. They also show that the incidence in both sexes is highest at the ages of 20 to 24. However, the height of the incidence in the women tends to develop slightly later in life than in the men, as is evinced by the fact that the frequency of lymphoblastoma becomes greater, after the age of 14, more rapidly in males than in the females. Likewise, the second highest point of frequency of lymphoblastoma in the females occurred at a later age (40 to 44) than the males (35 to 39). The disease appears to be relatively rare in males at the time of puberty (10 to 14 years of age), while the frequency of lymphoblastoma in females of this age and at the ages of 45 to 54, or the time of the menopause, is to be noted. A somewhat similar state of affairs appears to occur for that type known as chronic lymphatic leukemia, and the greatest age incidence for these patients is between 45 and 55.[1]

The age incidence of that form of lymphoblastoma known as Hodgkin's disease, to which males are especially susceptible, is shown in chart 4. The chart presents, with comparable age groups, Bunting's[4] data and the data for the 173 cases of the 477 of this series considered typical of Hodgkin's disease, as told by histologic examinations of a lymph node and the peripheral blood. The incidence of this condition is greatest in persons from 20 to 30. They comprise the majority of all cases of lymphoblastoma occurring at these ages, which are the ones at which the incidence for all forms of lymphoblastoma reaches its height. After the age of 30, there is a rapid decline in the occurrence of Hodgkin's disease, which takes place in an essentially constant manner. The relatively greater incidence of Hodgkin's disease in boys from 5 to 10 than in the five-year period before and after these ages is shown in both series of cases. Bunting has pointed out that the occurrence in females is greatest a few years later in

Table 1.—*Duration of Lymphoblastoma*

Number of Patients (Dead) Having Lymphoblastoma Less Than 10 Years, Arranged According to Age at Onset

	Age Groups in Years

[3] Schreiner, B. F., and Mattick, W. L.: Radiation Therapy in Forty-Six Cases of Lymphogranuloma (Hodgkin's Disease), Am. J. Roentgenol. **12**: 133 (Aug.) 1924.

[4] Bunting, C. H.: Diseases of the Lymph Glands, Nelson Loose-Leaf Medicine, New York, Thomas Nelson & Sons **3**: 347, 1920.

[5] The examinations were made by Drs. W. F. Whitney, J. H. Wright, F. B. Mallory, H. F. Hartwell, H. T. Karsner, S. B. Wolbach and E. W. Goodpasture.

[6] The term "onset" is used in this paper to indicate the time when the patient first had symptoms or signs that could be attributed to lymphoblastoma. It is recognized that the disease state must have existed earlier.

life than in males, and that there are relatively more instances of the disease in females among older persons. The present data show the same, but not so clearly as Bunting's. It may be noticed that the curve for the age incidence in males of our series rises faster than that for females, though the actual peaks for the two sexes fall in the same age group. The curve for the women then tends to fall somewhat more slowly than that for the men. When the data are plotted for the age groups 18 to 22, and 23 to 27, the distribution curves yield a peak for males in the first group and for females in the second, thus resembling more closely Bunting's observations.

The time in life when lymphoblastoma occurs with the second greatest frequency appears to be also somewhat later in females than in males. Thus, this state of affairs is quite similar to that for the height of the age incidence in males and females for all 477 cases and for those of that form called Hodgkin's disease, which comprise the majority of all cases of lymphoblastoma at this time in life. However, the second greatest age incidence of patients with lymphoblastoma is not dependent on the majority having Hodgkin's disease. This second peak is dependent especially on cases termed by some pseudoleukemia and lymphosarcoma. As recognized by Bunting, the decade between the ages of 30 and 40 is the particular time in life to find transitions from Hodgkin's disease to pseudoleukemia. Such records as those of Schreiner and Mattick,[3] indicating a second peak of age incidence for Hodgkin's disease, definitely suggest that the cases included are not of the same type as those given this name by others. The statistical facts recorded in the accompanying charts concerning the age incidence of patients with lymphoblastoma serve to emphasize what Bunting and others have noticed, that age and sex importantly influence the susceptibility of the lymphoid tissue to disease. These factors play a rôle not only in age incidence and occurrence of type of lymphoblastoma, but also in the rate of progress of the disease state.

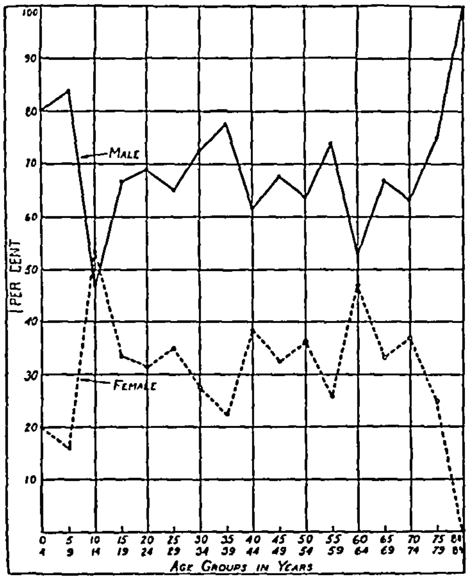

Chart 2.—Lymphoblastoma (477 cases, 327 males and 150 females): percentage of males and females in age groups of 5 years, arranged according to the ages at onset.

DURATION

Suitable irradiation with roentgen rays or radium is a distinctly beneficial form of treatment for patients with lymphoblastoma, bringing relief to many sufferers. Desjardins and Ford[2] have pointed out that it is not well known whether such treatment or other forms of therapy definitely prolong the life of these patients or not. Data bearing on this have been collected for the present series of cases and have been analyzed and studied together with some other aspects of the duration of lymphoblastoma. The influence of several factors on duration must be borne in mind, and the facts are presented from a general point of view, recognizing that errors arise in dating the onset of disease, that differences occur from year to year in so-called adequate treatment, and the like. Data concerning duration for all cases when plotted on probability paper give far from a straight line, clearly indicating that several factors must play a rôle and that there is no simple rule for predicting the duration of lymphoblastoma.

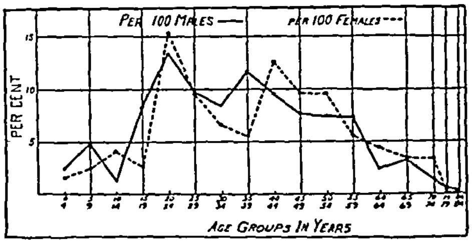

Chart 3.—Incidence of ages of males (solid line) and females (broken line) at the onset of lymphoblastoma

There were 163 patients of the 401 known to be dead that were not treated with any form of irradiation; thirty-three of these underwent a surgical operation with removal of a considerable amount of diseased tissue. The ages and the sexes of this group and the character of their disease states seem to be essentially the same as for 238 patients now dead who received treatment with either or both roentgen rays or radon.[7] Such treatment was given more often relatively late than early in the disease, though there were some first treated very early, but rather more were treated not long before death. The operations on the irradiated

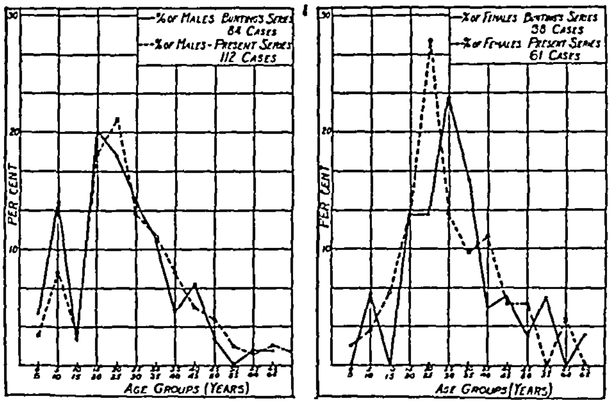

Chart 4.—Age distribution of cases of Hodgkin's disease, the percentage of males and the percentage of females in the different age groups of the present series (broken line) compared with Bunting's series (solid line).

---

[7] Roentgen-ray treatments were given at the Massachusetts General Hospital by Dr. George W. Holmes and his associates. At the Huntington Hospital, the roentgen rays were administered by Drs. R. G. Giles, M. C. Sosman and R. W. Vance, and the radon by various members of the staff.

and nonirradiated patients varied widely in nature; a few were very complete dissections with removal of all obviously diseased lymph nodes; others consisted of the removal of large lymphomatous masses. Details concerning surgical measures are not for discussion here, as only the trend of the course of lymphoblastoma will be considered. A surgical operation of a therapeutic sort was performed on thirty-four of the irradiated patients. There were a number of patients who took arsenic in some form both among those irradiated and among those not receiving such treatment. A few patients were transfused with blood. Many of the patients that were given irradiations did not receive what today would be considered the most suitable form or amount, while a few received irradiation that cannot be looked on as the best that might have been given at the time. However, as a group, these patients were treated systematically and their symptoms often were alleviated markedly. They serve as a series of irradiated patients for comparison with those not receiving such treatment.

Chart 5 illustrates the percentage frequency of the duration of disease not only for all 401 cases, but also for the males and females separately. Lines in this figure demonstrate the susceptibility of males to the rapidly fatal types of lymphoblastoma, and the likelihood that women will survive longer than men after the onset of the illness. In spite of the fact that the average duration for all cases is 2.76 years, there were forty-one patients (10.2 per cent) that had lymphoblastoma for six years or more before death; twenty-eight (11 per cent) of those irradiated, and 13 (8 per cent) of those not so treated. Seven (1.74 per cent), four irradiated and three that were not, lived more than ten years after the initial symptoms. The cases of long duration are given special consideration below.

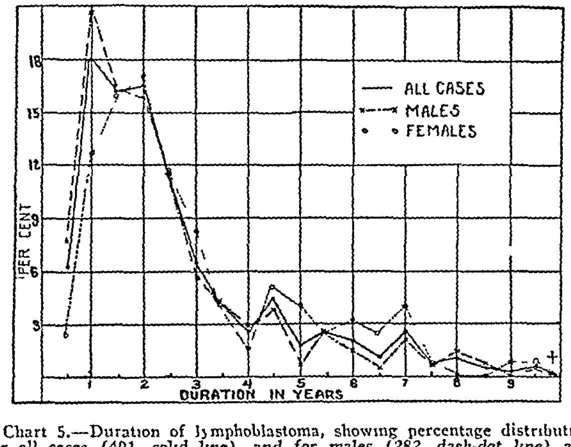

Chart 5.—Duration of lymphoblastoma, showing percentage distribution for all cases (401, solid line), and for males (282, dash-dot line) and females (119, broken line) separately.

EFFECT IN GENERAL OF IRRADIATION ON DURATION

A comparison of the duration of the disease in the irradiated and nonirradiated patients is shown in chart 6. These data suggest that this therapy has lengthened particularly the life of patients destined by nature to have their disease less than two and a half years, and has not influenced the course of those living long. Somewhat similar circumstances were met in studying chronic myelogenous leukemia.[8] There are, however, other ways to explain the differences. Patients with an acute form of lymphoblastoma that lasts a year or less probably soon become so ill that they are unable to reach a hospital where irradiation can be given; or it may be believed that their condition is so precarious that they are not referred for such therapy. On the contrary, it is probable that most patients with a relatively insidious onset of disease reach a clinic for irradiation. Thus, cases destined by nature to be of short duration would be more numerous in the nonirradiated group, and those fated to last long would become more often included in an irradiated group. That these may be the circumstances is suggested because the percentage number of patients living less than two years after the onset of lymphoblastoma for each group first seen in the periods of years 1900 to 1910, 1910 to 1915, 1915 to 1920, 1920 to 1925 +, was rather similar, though the highest percentage, not more than 8 per cent above the lowest, did occur in the ten-year period (1900 to 1910) before irradiation treatment was given at all. A comparison of the length of the course of disease in the four groups of patients first seen in these four different periods (making proper allowance for those now living) shows a very similar duration incidence. This suggests that in spite of the progressive improvement in irradiation methods, patients with lymphoblastoma recently have not had the disease run a longer course than it did fifteen years ago. The data concerning the seventy-six patients now living, and who, as a group, have had probably the best irradiation therapy, may be taken to indicate that this is not necessarily true. The chance for a long duration of their disease is more favorable than it was for the deceased when the probability of duration is taken into account with the time that they have already had lymphoblastoma.

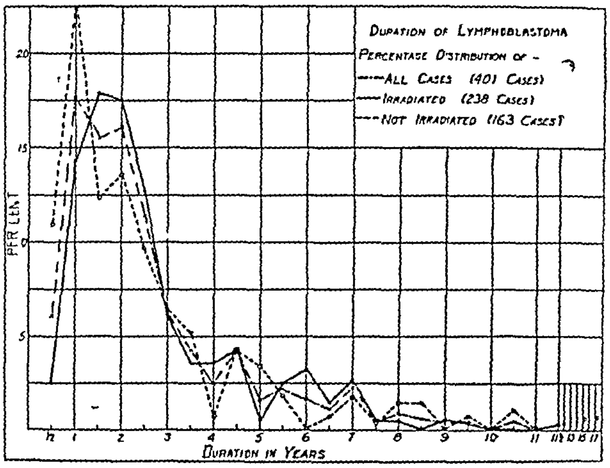

Chart 6.—Duration of lymphoblastoma: percentage distribution for all cases (401, dash dot line), and for the irradiated (238, solid line) and nonirradiated (163, broken line) patients separately.

A comparison of the data concerning the duration of the irradiated and nonirradiated deceased patients, plotted by the method of summation, shows that at any given time there was a greater percentage of patients living that were irradiated than were not. Even so, the differences at any period of duration are slight. The average duration of the disease in the 238 patients irradiated was 2.88 years, and in the 163 that were not, 2.45 years. The frequency of different durations of lymphoblastoma is almost exactly the same in the patients treated and those not treated by irradiation when only four groups are considered; namely, those having this disease less than three years, from three to six, from six to nine, and more than nine years. The influence of early irradiation on duration is reserved for consideration below.

[8] Minot, G. R.; Buckman, T. E., and Isaacs, Raphael: Chronic Myelogenous Leukemia: Age Incidence, Duration, and Benefit Derived from Irradiation, J. A. M. A. 82:1489 (May 10) 1924.

EFFECT OF SURGERY ON DURATION

The patients treated by surgical measures, whether or not they received roentgen rays or radon, had lymphoblastoma on the average 3.67 years, or 1.11 years longer than the average duration (2.56 years) of the disease in the 334 not undergoing a therapeutic operation. The chances of the former living beyond three years from the time of their first symptoms was greater than for the whole group of irradiated patients. However, the percentage dying a year or less after the onset of disease was the same as for the cases given no especial treatment, and only 10 per cent less than for the latter group at the end of the two-year period. A comparison between the duration of each of the thirty-four cases (average 4.07 years) treated surgically and by irradiation, and that of the thirty-three cases (average 3.25 years) treated only by surgical measures is shown by means of summation in chart 7. The plots show clearly that longer durations occurred in the former group. Such statistics can mislead one, and the following probabilities are to be borne in mind: Surgical procedures are apt to be undertaken chiefly when lymphoblastoma seems local or has progressed slowly or is not extensive. It is just such cases that seem destined by nature to last relatively long. Hence, it is difficult to state for a group of cases that surgical treatment was responsible solely for a long duration of the disease. That surgery alone or combined with irradiation can perhaps cure or play a most important rôle in extending the duration of a given case appears probable and is referred to later. The facts, however, especially as they pertain to the influence of a combination of surgery and irradiation in contrast to surgical treatment only, must also be evaluated cautiously. Some deaths occurred soon after operation. Such cases without previous irradiation would fall into the group of patients not irradiated, thus favoring the statistics for those that were irradiated. Again, in the irradiated group are patients who received no such treatment until long after a therapeutic operation, when the rays were used rather as a measure of last resort, so that very probably they did not influence duration.

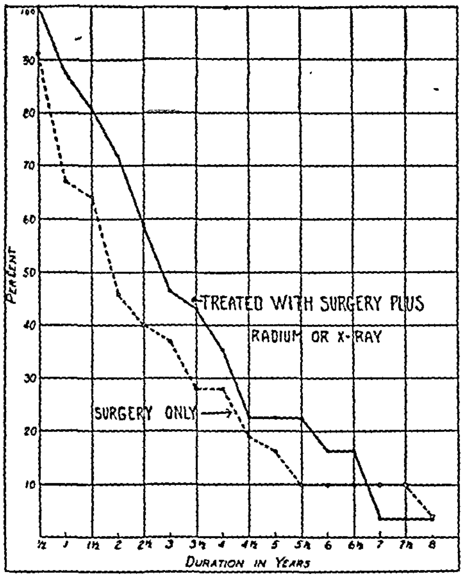

Chart 7.—Duration of lymphoblastoma: A comparison, by summation curves, of the percentage of patients living for given periods of time, with reference to whether they were treated by surgical measures combined with roentgen-ray or radium (thirty-four cases, solid line) or with surgery only (thirty-three cases, broken line).

(To be continued)

GENTLENESS IN GENITO-URINARY SURGERY

J. BAYARD CLARK, M.D.
NEW YORK

With the foregoing title in mind, I have stood on the edge of this short literary outburst for several years; years that have only emphasized the more the importance of this subject. Twenty years ago in the early moments of our fierce scientific surgical ardor, such a title would have seemed rather too effeminate to adorn a serious surgical essay. Today the situation is somewhat different, for the avoidance of trauma has come to have a new significance to the thoughtful student of contemporaneous surgery.

Back in days much earlier, when hospitals and surgical workshops were germ-ridden with organisms of exalted virulence, a surgical operation, with trauma or without trauma, was more likely than not to be followed by grave septic complications, and a fatal issue was a common conclusion. Then came the era that gave us antisepsis. Then asepsis itself came, with its marvelous results, as compared with the dark days of death dealing surgery before its advent. It can hardly be wondered at that the surgeon should for a time lose sight of that precious possession held by him in earlier days; namely, a deft and delicate touch. It is not at all surprising that so many great surgical teachers, elated with this new mastery of sepsis, assumed a boldness with the body tissues that placed them on strangely new pinnacles of fame. Naturally, these hardy masters had many ardent students who, with sterile gowns and gloves, emulated their methods. Had science not hit on the hidden secret of all that ghastly mortality of previous time? What had gentleness to do with the issue? Had not experience, hard on the heels of science and asepsis, proved that the germ and not the lack of gentleness was the one and great cause of infection and all the sorry sequellae of the surgeon's work?

Now it happened that the influence of this new boldness of surgical technic hit very hard on the field of medicine in which the then budding genito-urinary specialist was encamped. He, too, emulated the venturesome tactics of the famous masters; but, unlike the cutting, tearing, prying, delving and hard retracting surgeon, he was armed also with pushing, spreading, puncturing and probing implements which he used along the urethra, in the bladder and on beyond through the ureters into the kidneys. It is in the use of these instruments especially that this paper essays to deal. For again, unlike the general surgeon's problem of surgically clean methods, the genito-urinary surgeon has to deal with germ enemies resident along the urogenital canal, as well as those organisms of a pathogenic nature that remain after an infection has subsided and apparently disappeared. For him to traumatize the tissues in his instrumental manipulations means a lowering of tissue resistance and a breaking down of nature's defense mechanism against these invading or domesticated forces of germ enemies resident along the genito-urinary tract—a tract that cannot be prepared against infection as the skin is prepared for surgical procedure.

Bound up intimately with this question of using genito-urinary instruments in a manner that will not bruise the tissues and lay them open to easy invasion of infecting organisms is the larger subject of mental and nervous traumatism through fright, fatigue, fear, shock, apprehension, anxiety, alcohol and general anesthesia. Not a single one of these causes, which play major rôles in depression of tissue resistance and pave the way for local infection, can for a moment be lost sight of or forgotten by the urologist bent on attaining a high level of results. Crile's work on this important phase of surgery has added new luster to the intellectual side of American medicine, and workers in any branch of surgery cannot be said to be equipped who have not an appreciation of it.

A brilliant illustration of where we stand in this art is the mental reaction of any physician who is himself to be catheterized or examined with sound or cystoscope. If the genito-urinary surgeon wishes to find out exactly how the medical profession at large feels about the use of these necessary instruments today, let him have a few doctor patients who are in need of, let us say, a cystoscopy or a ureteral catheterization. He will soon find that he has on his hands patients filled with a pathetic fear of what they look on for themselves as a dreadful ordeal—an ordeal filled with the possibilities of excruciating pain, subsequent infection and, perhaps, irreparable injury. In consequence of this attitude rooted deep in their subconscious mind, it oftentimes becomes a well nigh impossible task to render them real service.

Next in difficulty of handling are those lay patients who have had experiences at the hands of inexperienced medical men in this realm of endeavor, persons who tell of a cystoscopy under a general anesthesia and of having been laid up in the hospital for days or weeks thereafter, recovering from the effects on their outraged and traumatized tissues.

Next to these comes the long line of patients traumatized by catheters, sounds or bougies. Notable among them are those brought to the hospital after fruitless attempts to relieve an acute attack of urinary retention, their urethras bleeding, congested and hopelessly blocked, and the stage all set for a serious infection. A surgical operation is forced on them, which might well have been avoided or postponed until they were carefully led up to the point at which it could have been performed with relative safety and success.

In larger numbers even come those patients whose strictured urethras have for years been subjected to reckless traumatizing and forcible dilation, suffering from each new adventure with increase of scar tissue and receiving in addition such sequelae as retention, infection of prostate or epididymis, and false passages. Can it be wondered at that, when the physician himself comes to face the necessity of a genito-urinary examination, he trembles with dread at the prospect, and the sphincteric sentinels of his bladder become as adamant as the fortifications of Verdun?

It does seem too bad that all this avoidable pain, suffering and infection, and the many escapable operations, with their consequent disability of vital functions, should not be brought into the focus of our more serious consideration—and held there. By gentleness, we can avoid virtually all the pain in connection with instrumentation. By gentleness, we can overcome the patient's apprehension, which unconsciously closes the external sphincter of the bladder. By gentleness in dealing with strictures, we can obviate splitting the scar and adding to it new fibrous tissue. By gentleness in cystoscopy, we can almost always avoid using anesthetics, which only blunt the patient's sensibility, our surest guide in avoiding traumatism with its many undesirable sequelae.

But even with gentleness in genito-urinary technic, a desirable state of affairs is not to be expected from those not sufficiently trained and experienced. Genito-urinary work is the one thing the young practitioner, as he starts in practice, looks to as his surest financial support. I should say it is the one thing that he is least fitted to attempt, for it seems the one medical branch of all others in which there is the greatest possibility of doing harm and inflicting permanent injuries. Many older practitioners "dabble," as they say, in genito-urinary work. How they have the temerity so exactly to express it is difficult to understand when one sees the results.

Perhaps one of the most serious situations of all from the standpoint of the patient and of the prestige of the profession of medicine as a whole is the practice of some general surgeons to assume the responsibility of serious genito-urinary surgical cases without the least equipment or training, other than their ability as operators. This practice is a two-edged sword; for they not only will not bother to learn the essential preoperative and postoperative factors entering into the problem of these cases, thus lowering the standard of attainable end-results, but they keep from the hands of the earnest young genito-urinary surgeon much operating room work essential for him to have to be sufficiently skilful in this lesser aspect of the problem, the operative technic.

If the general surgeon sincerely believes that the surgery of the genito-urinary tract should be included in his field and excluded from the smaller but highly technical branch assumed by the specialist, there can be no possible objection to his training himself to equal proficiency in the diagnostic and preoperative responsibility, and to his learning to see his patients out of their difficulty after operation. Divided responsibility here, as in other leading walks of life, is not the soundest plan.

The time has come when a sincere consideration of such subjects as these is no longer possible to postpone. There is good reason why there are so many other cults pioneering in the broad field of the healing art. If complete public confidence is to be restored to the profession of medicine, it will have to be merited by the quality of services rendered all along the line.

Medical Practice of Primitive Tribes.—Primitive tribes existing at the present day show in their medical practice features closely comparable to those found everywhere in the medicine in antiquity. Disease is ascribed to the action of supernatural agents or of human magic, and treatment is carried out mainly by incantation, ceremonials and exorcisms, but again we find a number of remedial practices, apparently divorced from the demonological theory and therapy, and including the use of drugs and such simple measures as poulticing and bloodletting.—Hart, Bernard: *Lancet* **1**:586 (March 20) 1926.

SCARLET FEVER

AN ANALYSIS *

JANVIER W. LINDSAY, M.D.
E. CLARENCE RICE, M.D.
AND
MAURICE A. SELINGER, M.D.
WASHINGTON, D. C.

In presenting this analysis of the work of the scarlet fever ward of the Garfield Memorial Hospital, we recognize that many points require much further study; but certain facts seem to be of sufficient importance and sufficiently clearly demonstrated to justify offering them as additional evidence in support of reports already published and to which our results appear to correspond. While we shall not refer at length to papers that have appeared, we are indebted to the workers who have made available the newer methods for the study and management of one of the most dreaded diseases and to those who have generously supplied us with materials.[1]

We have been interested in the various phases of the scarlet fever problem, including the intracutaneous test, after the method of the Dicks, both for susceptibility and for diagnosis, the Schultz-Charlton blanching test, the attempt to produce active and passive immunity, and treatment by the specific antitoxin.

THE INTRACUTANEOUS TOXIN TEST

Except in the early period of the study, there has been no difficulty in adjusting the concentration of the toxin for the Dick test so that a true determination of susceptibility or immunity might be obtained. The fact that a given specimen actually possessed toxic properties was readily shown by injection into the skin of a number of susceptibles, and the permissible concentration was controlled by similar injections in a number of known recovered scarlet fever patients. A valuable aid also was the plan of making successive intracutaneous injections of toxin, at intervals of several days, in patients acutely ill with scarlet fever, the very early test usually giving a positive result, and the later ones becoming progressively less marked until a definite negative reaction was obtained. This procedure is not only a guide to the regulation of the proper skin test dose, but is also a demonstration of the specificity of the toxin.

It cannot be too strongly emphasized that tests of the type of the Dick test should always be made in groups, so that a series of controls may be had for each observation and for each lot of toxin used. It has been our good fortune, through the courtesy of the Public Health Service, to have a supply of its standard toxin. This preparation has been used in duplicate tests by simultaneous injection with a second toxin in seventy subjects, and the reading has corresponded in all but four instances, two of these being in the early stage of the study when the second toxin proved too strong, as it was then prepared. The second toxin practically always gave a more marked reaction than that resulting from the Public Health Service standard. As there appears to be a considerable range of safety between the limits of which a truly diagnostic serum may be adjusted, that is, without danger of false positive or negative reactions, we have rather favored the stronger concentration, as giving more definite and more readily classified readings, a factor of considerable importance in applying the test to dark skinned races, such as the negro. In those cases in which a difference in reading occurred, the Public Health Service standard gave a negative and the second toxin a positive reaction, of faint or moderate degree.

We have no knowledge that any of the subjects, tested by either of these toxins and considered immune, have later developed scarlet fever, and our attitude in advocating the more concentrated toxin is based rather on theory than on definite evidence; but it is our feeling that the use of the higher concentration, properly controlled by tests on known recovered patients, may better insure the recognition or detection of a small percentage of susceptibles who may possess sufficient natural antitoxin to neutralize the toxin contained in the more dilute preparation.

That there is a great variation in the amount of natural antitoxin in different persons is well brought out in a series of Dick tests, and this point should be constantly kept in mind, for, as will be described later, the use of a large dose of toxin for active immunization of a susceptible in whom an unusually marked local reaction indicates the presence of an unusually small amount of natural antitoxin may lead to startling results, if not to actual danger.

In a series of 284 intracutaneous tests, 109 were positive, 175 negative, eighteen pseudonegative and nine combined positive. The protein factor, when present in the pseudo and combined reactions, did not cause confusion, as the toxin and control areas corresponded closely in appearance in the former, and the toxic, superimposed on the protein reaction area, was clearly contrasted with the purely protein reaction area of the control in the latter. In connection with the subject of the combined reaction, we would mention again our belief in the advantage of the stronger concentration of toxin.

No instance of an immune having subsequently contracted scarlet fever, as determined by the intracutaneous test, has occurred in this series, so far as we know. On the other hand, eight found to be Dick positive and therefore considered susceptible have since developed the disease. The fact that the subjects of these tests included a number of nurses and medical students who afterward were directly exposed to scarlet fever in the wards has added interest to the study of the results.

The successive intracutaneous injections of toxin, already referred to in connection with the adjustment of the dose for use in the Dick test, have also, in a number of instances, helped to clear up doubt as to diagnosis. This procedure, if begun early in the illness, may well be the means of preventing exposure of a susceptible, suffering from some disease simulating scarlet fever, to the danger of infection from too hasty admission to the ward, on the basis of clinical study alone. On the other hand, the evidence that a patient was immune when placed in the scarlet fever ward or the reinforcement of the clinical diagnosis by the single or repeated Dick test may help to relieve the attending physician or institution of the burden of criticism frequently associated with supposed errors in this type of disease. We would hesitate today to make a diagnosis of scarlet fever in a patient previously well, who, promptly after tonsillectomy, some other surgical pro-

---

[1] All materials not otherwise specified in the text were supplied through Eli Lilly & Co., Indianapolis.

cedure, or a severe burn, developed a rash, with or without angina and nausea and fever, until the clinical evidence has been supported by the appropriate use of the Dick test.

SCHULTZ-CHARLTON TEST

The rash extinction test of Schultz-Charlton has been of some interest with regard to diagnosis and also as a means of judging the potency of antitoxins

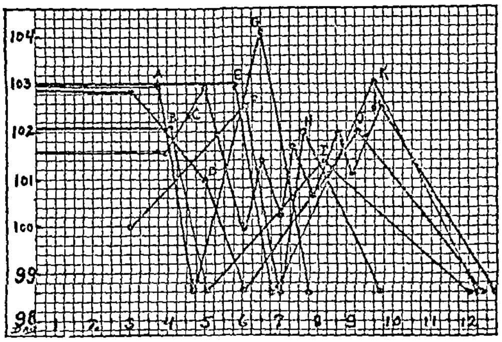

Chart 1.—Antitoxin dosage in patients showing no severe complications: *A*, 15 cc. (II); *B*, 25 cc. (II); *C*, 10 cc. (III); *D*, 30 cc. (II); *E*, 40 cc. (I); *F*, 10 cc. (I); *G*, 25 cc. (III); *H*, 10 cc. (I); *I*, 25 cc. (II); *J*, 40 cc. (I); *K*, 35 cc. (III), and *L*, 10 cc. (III). Average fever period, 10.6 days. In the charts, the type of antitoxin is indicated by Roman numerals: I, prepared by Dochez; II, Lilly unconcentrated; III, Lilly early unconcentrated; IV, Lilly new concentrated, at least 30,000 to 50,000 skin test doses per cubic centimeter.

used in treatment. When several lots of antitoxin have been at hand, we have used in a given case the one that gave the best blanching reaction when either or both produced a positive result. As the result of this procedure is much affected by the time at which it is carried out with relation to the onset of the illness, and as a local protein reaction frequently renders the test useless, we have depended less on this than on other methods of studying both of these problems. From a rather limited number of observations, we have concluded that a positive blanching test doubtless indicates some degree of antitoxic potency in a serum, but that a failure to blanch the scarlet rash does not necessarily indicate that the serum will not prove to be an efficient antitoxin, even in the case in which it gave the negative result.

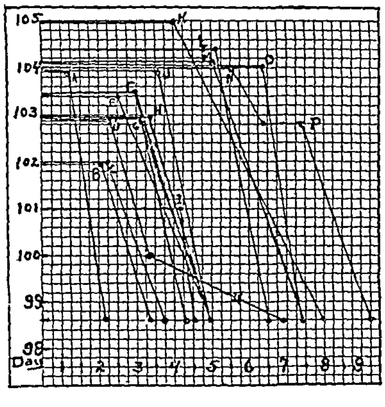

Chart 2. — Antitoxin dosage in patients showing no severe complications: *A*, 40 cc. (II); *B*, 40 cc. (I); *C*, 10 cc. (I); *D*, 40 cc. (III); *E*, (IV); *F*, (IV); *G*, 15 cc. (II); *H*, 40 cc. (II); *M*, 40 cc. (I); *N*, 40 cc. (I); *O*, 40 cc. (II); *P*, 40 cc. (I). Average fever period, 5.4 days. *X*, case with inpetigo.

IMMUNIZATION

In the field of immunization, our concern has been rather with the active than with the passive method. Several prophylactic injections of antitoxin have been given, but, even in a very limited series, what appear to be quite contrary results have been seen. One patient developed scarlet fever within four weeks after the inoculation. She had not been retested for susceptibility after the antitoxin had been given, so we do not know definitely that she had been immunized at all. Two other subjects, shown to be strongly Dick positive, became Dick negative within three days from the time of injection and were still negative eight weeks later. In view of the uncertainty of immunity from this method and the possibility that the antitoxin injected for this purpose may neutralize toxin later given to produce active immunization, it seems best at this time to proceed with the active method as early as possible, if any attempt is to be made to develop protection in a susceptible individual, remembering, of course, that it may take some weeks for immunization to be established. As previously stated, the work of active immunization included a group of nurses and medical students. We shall refer chiefly to these, with a few others whom it has been possible to observe continuously and to retest several times, the data thus obtained appearing to us of more value than a larger group, the subsequent history of which is indefinite or unknown.

To each of a group of fourteen susceptibles thus selected, three injections of toxin were given subcutaneously, the first dose of twenty-five skin test doses, the second of sixty-five and the third of 125. As this dosage was based on the skin test dose as indicated by the more concentrated toxin, the figures would be about three or four times as high in terms of the Public Health Service standard. On retest six weeks later, all the nurses so inoculated were found to be Dick negative. Two medical students and three children were still positive, although there was a marked reduction in the intensity of the reaction in all but one.

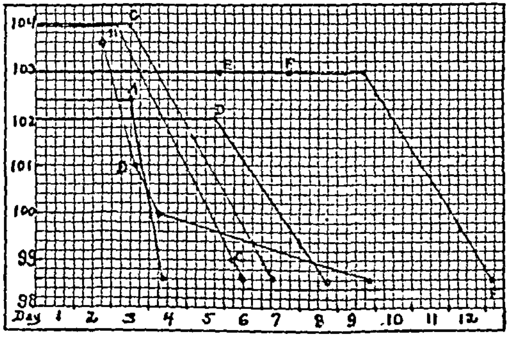

Chart 3.—Antitoxin dosage in patients showing no severe complications: *A*, 40 cc. (II); *B*, 25 cc. (III); *C*, 30 cc. (II); *D*, 25 cc. (II); *E*, 40 cc. (II); *F*, (IV); *G*, 40 cc. (III). Average fever period, 6.4 days.

At this time the plan was adopted of assigning to duty in the scarlet fever ward only those nurses who had been found to be Dick negative either because of natural immunity or as a sequel to toxin injection. One of the nurses, who had been found to be Dick positive and who failed to report for immunization, was inadvertently assigned to the ward for active service. She developed typical scarlet fever shortly after entering on duty and was the only nurse who had scarlet fever during the period of our analysis. No member of the immunized or probably partially immunized group just described has had scarlet fever.

Several nurses, including some naturally immune and some actively immunized, had sore throat with fever during their service in the scarlet fever ward, but all gave clearly negative skin tests made immediately on appearance of symptoms; none had a rash or other clinical evidence of the disease; none desquamated and all returned to duty, apparently well, in a few days.

By contrast, in 1920 four nurses, in 1921 eight, in 1922 seven, in 1923 six and in 1924 five were ill with typical scarlet fever while serving in the ward. Of the thirteen comprising the special group described, in whom the attempt at active immunization was attempted, eleven were available for retest after ten months. Two could not be reached, but are known not to have had any illness resembling scarlet fever. Eight were still Dick negative; three highly susceptible children were still positive, though to a less degree than at the first test, and one nurse, negative at the first retest after inoculation, showed a very faintly positive reaction at this time. It appears to us that even with the imperfect understanding of dosage and method at first used, the procedure has been amply justified. With the more intensive plan now in use and a better distribution of dosage, more satisfactory results from the standpoint both of percentage of successful immunization and of permanence of protection may well be anticipated. We are now employing from four to five doses of toxin, at weekly intervals, beginning with 250 to 500 and increasing each dose to make a total of 20,000 to 30,000 skin test doses, respectively, these, as before, in terms of the stronger toxin.

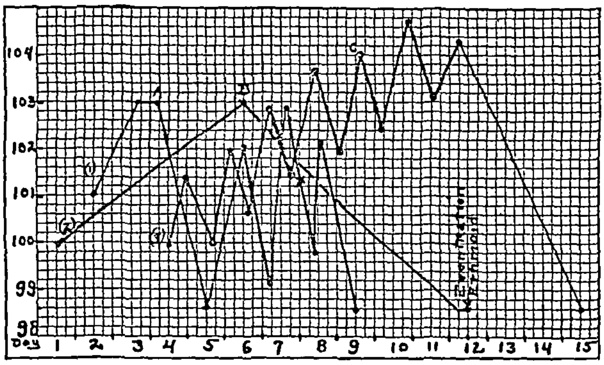

Chart 4.—Antitoxin dosage in cases showing severe complications: *A*, 30 cc. (III); *B*, 10 cc. (II); *C*, 25 cc. (II). Average fever period, 11.5 days. *X*, discharge from right ear.

In connection with the discussion on adjustment of toxin concentration for making the Dick test and on the variation in amount of natural antitoxin in different individuals as indicated by the test, a case of especial interest was cited which we feel warrants more detailed description. The patient gave the largest and most intense Dick reaction we have seen, the local area of erythema being five or six times that found in the average test. A few days after injection of the usual first dose of toxin subcutaneously, that is, twenty-five skin test doses, and following a marked local reaction at the point of injection, there was general malaise of an unusual degree, moderate fever, nausea, headache, edema of the face and hands, and a definite, diffuse, smooth erythema, strikingly like the rash of scarlet fever in color. Later there was desquamation, and albumin was present in the urine temporarily. As the patient had been exposed to scarlet fever a short time before, the possibility of a coincident infection was considered; but, as the Dick test was still positive on repetition six months later, it seems clear that the disturbance was a reaction to a dose of toxin relatively large in proportion to the amount of natural antitoxin present in the body. Only the one dose of toxin was injected in this case.

ANTITOXIC THERAPY

Although we have encountered some difficulty in completely classifying the cases of scarlet fever treated with the specific serum and in placing them in definite groups with reference to the results obtained, certain lessons have been impressed on us, consideration of which may have a part in carrying out the purpose of this analysis. We believe the data recorded below bear out the published opinion of others that a true antitoxic serum has been produced.

The Schultz-Charlton reaction is a graphic means of demonstrating the antitoxic properties of a given serum. Further, in a group of seven susceptibles, a series of intracutaneous injections were made, using two toxins, one injection of a single skin test dose, and four other injections of varying mixtures of toxin and antitoxin, in each subject. In most instances both toxins were used, in two cases only one. It was found invariably that, as the proportion of antitoxin in the mixture was increased, the corresponding local reaction diminished in size or intensity or in both, even to the extent of completely negative Dick tests in most of the group, at the site of injection of the highest antitoxic concentrations.

During the fourteen months from Nov. 1, 1924, to Dec. 31, 1925, inclusive, more than 300 patients with scarlet fever were cared for at this hospital. In our study, a few cases followed under practically the same conditions of observation but not in the hospital are included. Of the entire number, thirty-five patients were given antitoxin. Three of this group are considered apart from the rest, as they were in such condition on admission that no definite or permanent effect from the use of serum could be anticipated. One of these was moribund, with pneumonia following childbirth, and died within about six hours after entering the ward. One patient (case 1, chart 5) was ill with bronchopneumonia when admitted, but recovered, a sharp though temporary drop in temperature having occurred immediately after injection of the antitoxin. The third of this separate group (case 2, chart 5) had had a fracture of the elbow before coming to the ward and was already suffering from a severe arthritis when first seen. The fracture had been considered a part of the arthritis for a number of days before admission and had caused a considerable amount of pain.

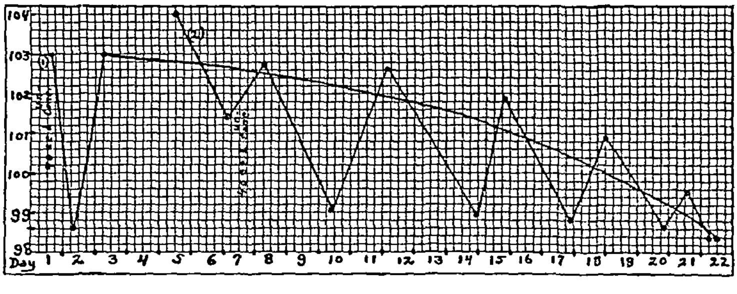

Chart 5.—1, pneumonia well established on admission; 2, arthritis, marked on admission and elbow fractured just before admission.

Charts 1, 2 and 3 represent the patients treated by antitoxin in whom there were no complications of severe degree, while chart 4 shows those who did have serious complications,[2] and chart 5, the patients with pneumonia and arthritis, who recovered and who were just referred to. The letters on the charts represent the points at which doses of antitoxin were given; the vertical numerals are degrees of temperature and the horizontal, days of the disease. The amount of each injection of antitoxin is stated in the legend below the chart. In the case of antitoxin IV, the number of cubic centimeters varied, but the dose always represented sufficient to neutralize at least from 30,000 to 50,000 skin test doses, of the stronger type already mentioned, per cubic centimeter, or a total dose to neutralize at least 250,000 skin test doses.

---

[2] Complications included such conditions as otitis, mastoiditis, acute parotitis, ethmoiditis with necrosis, cervical adenitis of very severe degree, pyelitis, arthritis and nephritis.

Examination of the curves in chart 1 shows one case in which the temperature, after approaching normal, later followed a more gradual decline than at first. This patient had an extensive impetigo involving practically the entire body, and only with the clearing up of this condition did the temperature become finally established at the normal level. It will be noted that all but two of the patients represented in chart 1, and one represented in chart 3, were given two doses of antitoxin, and one in the chart 3 group was injected when the temperature had reached normal. We are satisfied that the temperature course subsequent to the various doses of antitoxin as here illustrated is more than a coincidence and must have resulted from the effect of the specific antitoxin administered. In only two instances in the groups shown in the first three charts was the injection not followed by a definite and generally continuous return of the temperature to normal, and one instance in which no effect was observed, although the temperature was high and the other when the temperature was already normal. These two cases are included, however, because we believe they bear on the problem of the relation of antitoxic treatment to the frequency of complications.

Two deaths among scarlet fever patients occurred. One of these patients was moribund, with pneumonia following childbirth, and, as stated, died a few hours after the injection of the antitoxin, and the other, in desperate condition from pneumonia, was admitted and was not given antitoxin. One other patient, ill with pneumonia when the antitoxin was administered, recovered, the temperature course being shown in chart 5, case 1. The comparatively low number of deaths in a series of 300 cases of illness of the type of scarlet fever forcibly emphasizes, by contrast, the well recognized importance of the complications as commonly encountered, and any measure which reduces the number and severity of those complications must be looked on as an important advance.

Study of the patients not treated with antitoxin during those fourteen months reveals an average incidence of complications of 17.7 per cent for the entire series. This percentage varied slightly for different periods, that for November and December, 1924, being 16 per cent; from January to April, 1925, inclusive, 22 per cent; from May to August, 1925, inclusive, 16 per cent, and from September to December, 1925, inclusive, 12.6 per cent. On the other hand, comparison with the condition in the treated patients suggests some interesting data. Including all patients but the two previously mentioned having pneumonia and arthritis, only 10 per cent of those receiving antitoxin developed serious complications. Close examination of the history, physical findings and temperature curves in cases 2 and 3 (chart 4) have convinced us that in these instances also the antitoxin was not given until after the onset of the complicating condition, in the one case a severe adenitis, in the other definite necrosis of the ethmoid. Leaving these two patients out of the group of complications beginning after the administration of antitoxin, the incidence of complications in the treated patients is 3.5 per cent.

The difference in frequency of complications in the treated and untreated patients is the more striking, as the number selected for use of the serum included only those deemed particularly ill, while those developing complications among the group not receiving serum included many of the mildest type.

With regard to the effect of antitoxin in shortening the period of acute illness, we have, of course, used the temperature course as one index. The average duration of fever in the patients in chart 1, most of them having had two doses of serum, was 10.6 days. The second injection was undoubtedly required in many of these instances because of the small amount given at first, a fact which, in our opinion, accounts for an unnecessarily long febrile period. Those in chart 2, including the case of impetigo, had an average of 5.4 days of fever, those in chart 2, 6.4 days, and the group with complications as shown in chart 4, 11.5 days. For all cases in which antitoxin was given, except the two originally excluded, the average fever period was 7.6 days, or excluding also cases 2 and 3, (chart 4), 7.3 days. The average number of fever days for the untreated patients, not including the rises of temperature accompanying many of the later complications, was nine.

While there is, therefore, an apparent gain in the average case in favor of the antitoxin with reference to the shortening of the fever period, we would emphasize again that we believe the course of the temperature following the injections is of more significance than the mere duration of fever. We are the more impressed with the correctness of this opinion when we consider the almost invariable accompaniment of slowing of pulse rate, the improvement in character of the pulse and the favorable alteration in clinical condition, strikingly similar to the changes so familiar in the treatment of diphtheria with the corresponding antitoxin.

The serum reactions have not been more severe than have been seen with diphtheria antitoxin, and the frequency and severity of these seem to be diminishing as advance in concentration methods is accomplished. We would urge caution in the matter of dosage of antitoxin, favoring rather larger doses, possibly twice that now recommended by the manufacturers, given at the earliest possible moment, rather than the smaller doses to be repeated if indicated. We are now using sufficient to neutralize between 750,000 and 1,000,000 skin test doses of toxin. All the antitoxin that we have used has been prepared after the method of Dochez, and a supply of material prepared by Dr. Dochez himself was included. Our series has not been sufficiently large and the conditions of administration have varied to such an extent that we will not venture an opinion as to which special lot of serum has given the best results, and we are now observing a series of cases treated with the most recent type of material prepared by the Dochez method and with concentration by methods similar to that used in the preparation of the diphtheria antitoxin. The results, as far as we can predict at this date, seem to compare favorably with those outlined in the foregoing analysis.

CONCLUSIONS

1. The intracutaneous injection of properly concentrated scarlet fever toxin, after the method of the Dicks, properly controlled by use in groups, is a reliable means of determining susceptibility or immunity to scarlet fever.

2. This method is also frequently of definite assistance in diagnosis.

3. It is possible actively to immunize susceptibles for a considerable period.

4. Care should be used to adjust the dose of toxin for active immunization so as to avoid serious reactions in those who may have an unusually small amount of natural antitoxin, as indicated by an unusually large and intensely positive Dick reaction.

5. There is ample evidence that the serum prepared by the method of Dochez now available for the treatment of scarlet fever possesses true and specific antitoxic properties in effective concentrations.

6. The early use of sufficient amounts of antitoxin apparently reduced the incidence of complications of severe degree.

7. A single large dose of antitoxin will probably prove more satisfactory, from every standpoint, than a small or moderate dose with the possibility of repetition.

8: The intramuscular injection appears to be satisfactory in practically all cases, the intravenous possibly being indicated in critical conditions.

9. We suggest the advisability of testing all patients for sensitiveness to serum before giving the antitoxin, even though workers are not in complete agreement as to the importance of this procedure.

THE NASAL PASSAGES IN LOBAR PNEUMONIA

A CLINICAL AND BACTERIOLOGIC STUDY *

A. R. FELTY, M.D.
HARTFORD, CONN.
AND
C. A. HEATLEY, M.D.
BALTIMORE

The frequency of pneumococcal infection of the paranasal cavities in lobar pneumonia was noted by Darling[1] in 1906, when he demonstrated acute inflammatory changes due to that organism in one or more nasal sinuses in more than 90 per cent of a series of pneumonia cases in which he performed necropsies. These findings have been confirmed in a much larger series of necropsies.[2] Darling's belief was that "the portal of entry of the pneumococcus in most instances is an accessory nasal sinus, the mucous membrane of which is probably fitted for the reception of the pneumococcus by an antecedent influenza or rhinitis." Little investigation has been made of the nasal passages and sinuses during the course of lobar pneumonia. In a series of thirty-five cases, Stillman[3] took cultures of the nose by introducing a swab into the nostrils, and in fifteen cases isolated the pneumococcus, though not always of the same type as that recovered from the sputum. No reference has been found in the literature to clinical observations of the nasopharynx in this disease.

In this study, nasopharyngoscopic examinations were made in a small group of cases of lobar pneumonia. Wherever possible, the sinuses were studied roentgenographically. Simultaneously, cultures of the nasal passages were made in an effort to correlate, if possible, the bacteriologic and clinical data thus obtained.

METHODS

The nasal passages were first examined through a speculum. The mucous membranes, which were usually edematous, were then shrunken with pledgets moistened with cocaine (10 per cent solution) and epinephrine (1:1,000). A satisfactory view of the middle and superior meatus was thus obtained. Examination was made with a nasopharyngoscope giving a direct image. In some cases anteroposterior roentgenograms of the sinuses were taken. Cultures were obtained by applying a swab beneath the middle turbinate bone on each side, a sterile nasal speculum being used and contact with the tissues of the vestibule being avoided. The material was thus obtained at the point of drainage of the maxillary, frontal and anterior ethmoid sinuses. The material was injected into the peritoneum of a mouse, and in certain cases cultures were grown on rabbit's blood agar plates (p_H 7.8). The pneumococcus obtained was typed by agglutination with the three serums, and bile solubility was determined. The pneumococcus isolated from the sputum was studied by the same method. Blood cultures were made on all patients.

Eleven patients, four of whom had never had pneumonia, and seven of whom had had the disease in the hospital within the preceding eighteen months, were used as controls. Cultures of the nasal passages were taken, the material being obtained from the middle meatus on each side. In nine of the eleven cases, no pneumococci were isolated from the nose. From two of the patients who had previously had pneumonia, pneumococcus type IV was obtained, which did not correspond to the type that had caused the disease.

In ten cases there was obtained a history of an antecedent rhinitis of from three to fourteen days' duration. In a few instances, the patients had noted frontal or general headaches. In view of the fact that most of these patients were unintelligent and presumably unobservant, this percentage is probably lower than it might have been if the patients had belonged to a more educated and selected group.

The occurrence of rhinitis preceding the onset of pneumonia has been noted by many writers. In Cole's[4] large series, almost 40 per cent of the patients gave a history of coryza antedating the pulmonary infection. Cole says: "When patients are carefully examined, it will be found that, in a surprisingly large number of instances, symptoms referable to the respiratory tract have preceded the actual onset of the disease for a period of a few days to several weeks."

Patients seen early in the disease uniformly showed diffuse hyperemia of the entire mucosa. The mucous membranes of the turbinates were commonly swollen and engorged, so that the breathing space was often greatly reduced. Tiny bleeding points representing superficial ulcerations were seen in some cases. Mucoid discharge along the floor of the nose was occasionally observed. In six cases there was a frankly purulent discharge around certain of the sinus orifices (usually the maxillary, frontal and anterior ethmoid).

While it was hoped that roentgen-ray examination of the sinuses might be obtained in every case, this was not possible in numerous instances on account of the severity of the patient's illness, or the inability of the patient to assume the position necessary for the proper exposure, or for other considerations. In the eight cases in which the sinuses were roentgenographed, seven showed clouding of one or more nasal sinuses. In the

one case in which the sinuses were "clear," the examination was not made until the second day after the crisis. In five of the seven cases, nasopharyngoscopic examination indicated the presence of purulent sinusitis. The two other cases showed hyperemia of the mucous membranes, one with mucoid discharge. It seems highly likely that had lateral and anteroposterior roentgenograms of the sinuses been made in all cases, other instances of sinus involvement might have been recognized.

Table 1.—*Results of Nasopharyngoscopic and Roentgen-Ray Examinations*

Nasopharyngoscopic Examination	Roentgen-Ray Examination	
Purulent discharge	"Clouding" of sinus	5
Hyperemia and mucoid discharge	"Clouding" of sinus	1
Hyperemia	"Clouding" of sinus	1
Purulent discharge	Not made	1
Hyperemia	Sinuses "clear"	1
Hyperemia and mucoid discharge	Not made	2
Hyperemia	Not made	4
Not made	Not made	1
